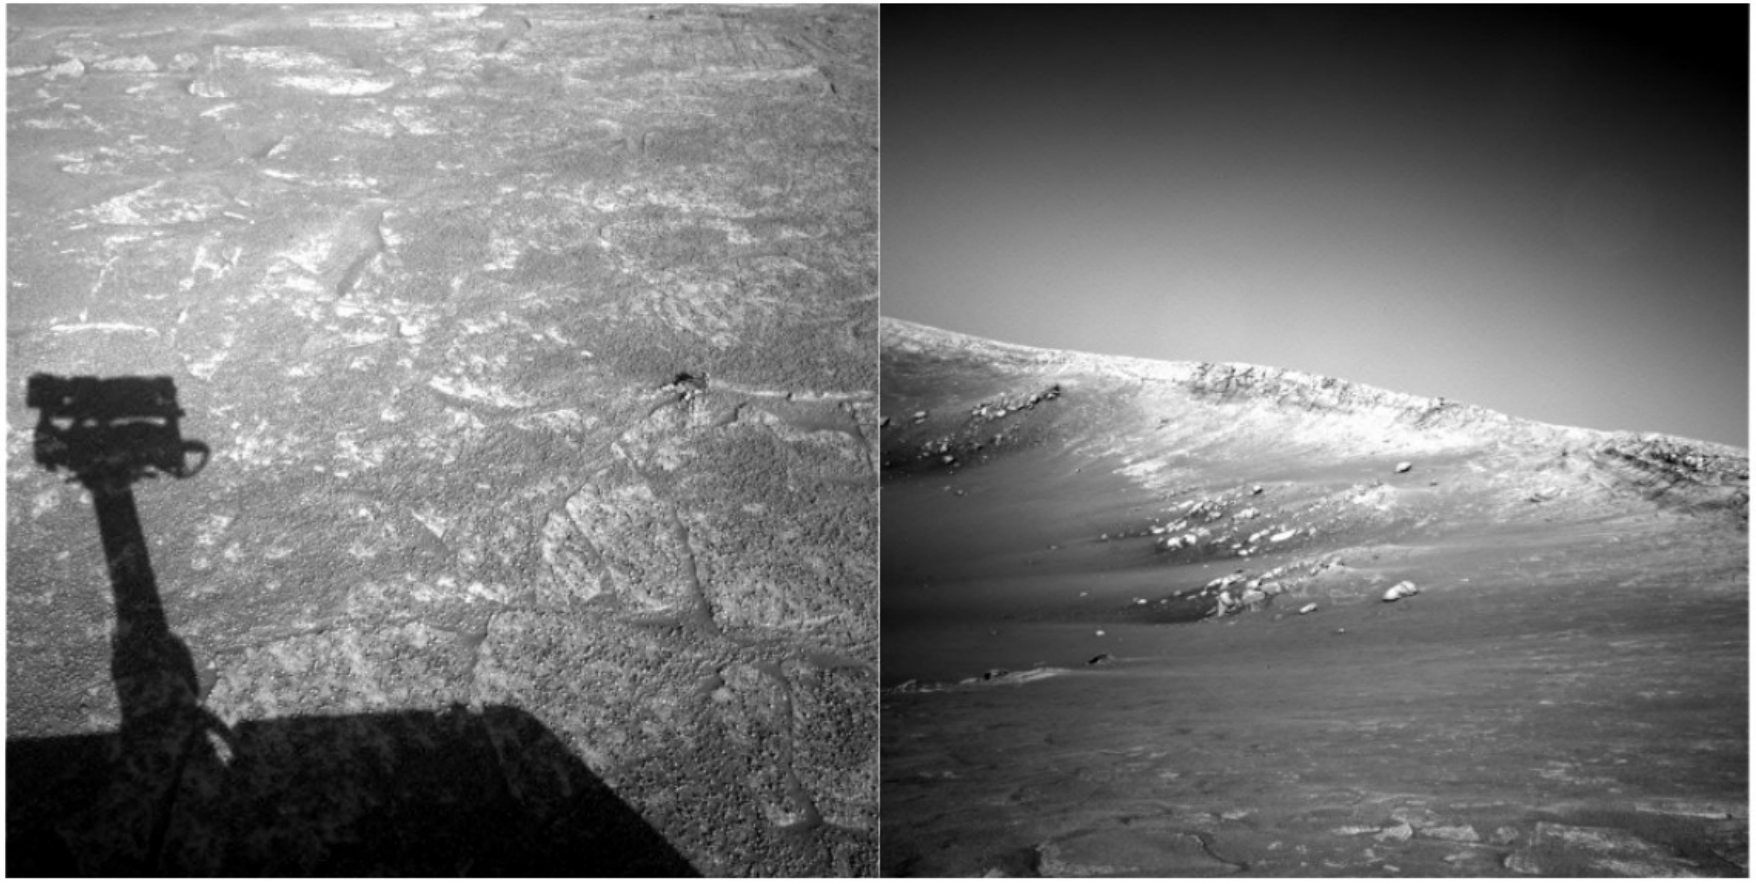
Beyond Stereo Vision

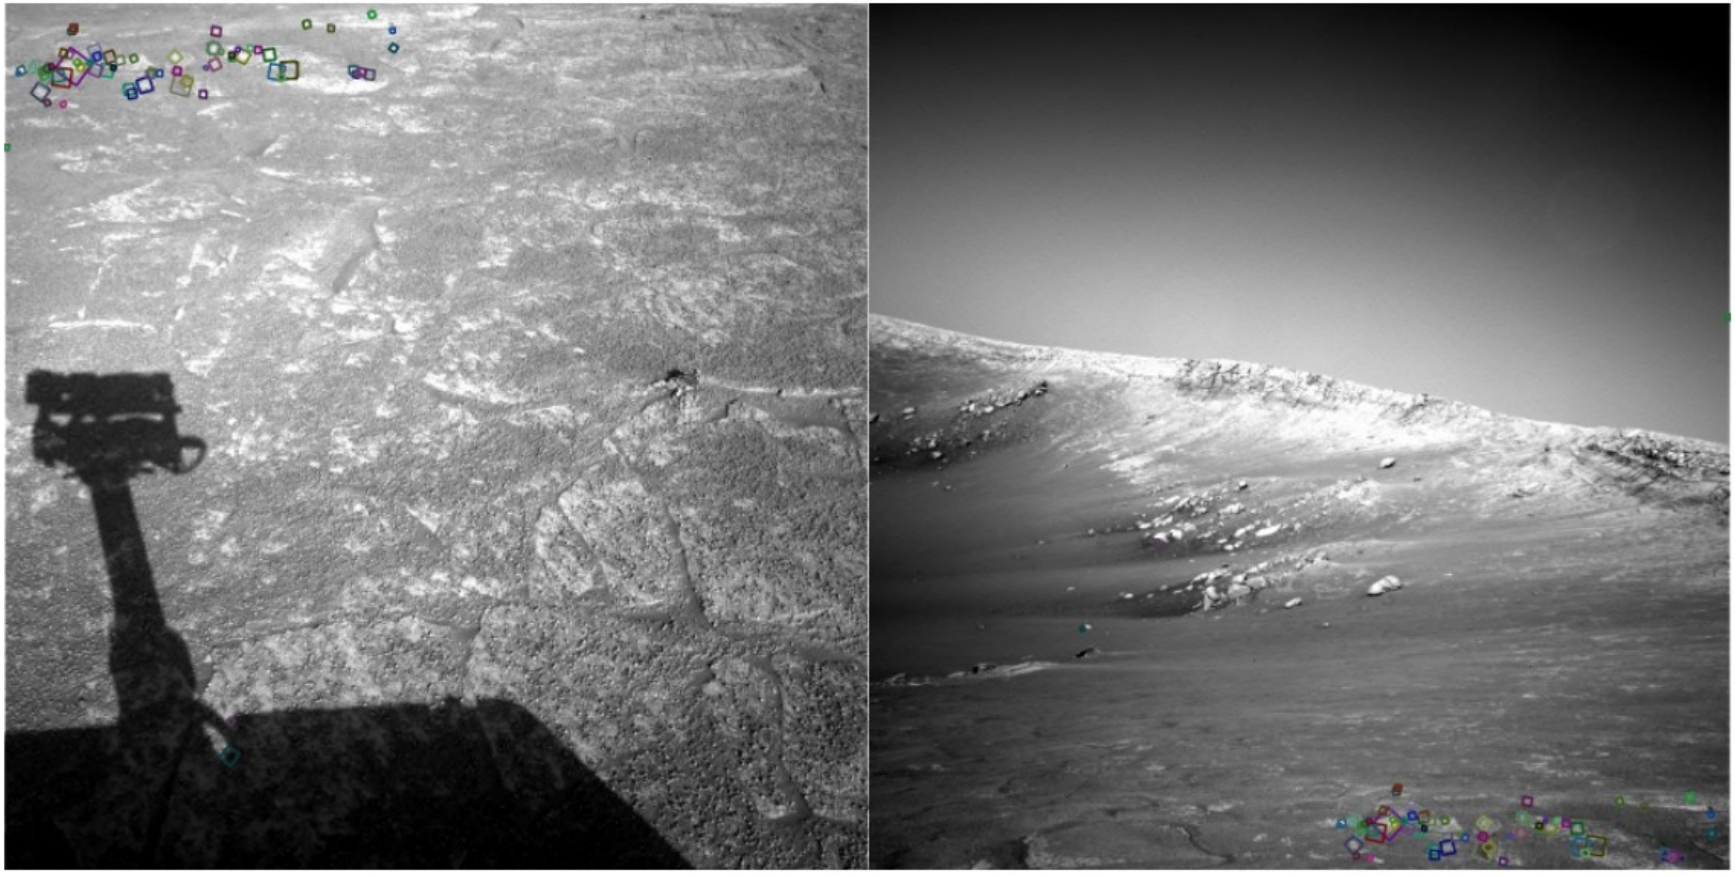
UNIVERSITÀ DI PARMA



NASA Mars Rover images

Beyond Stereo Vision

UNIVERSITÀ DI PARMA



NASA Mars Rover images with SIFT feature matches

Characteristics of a good feature

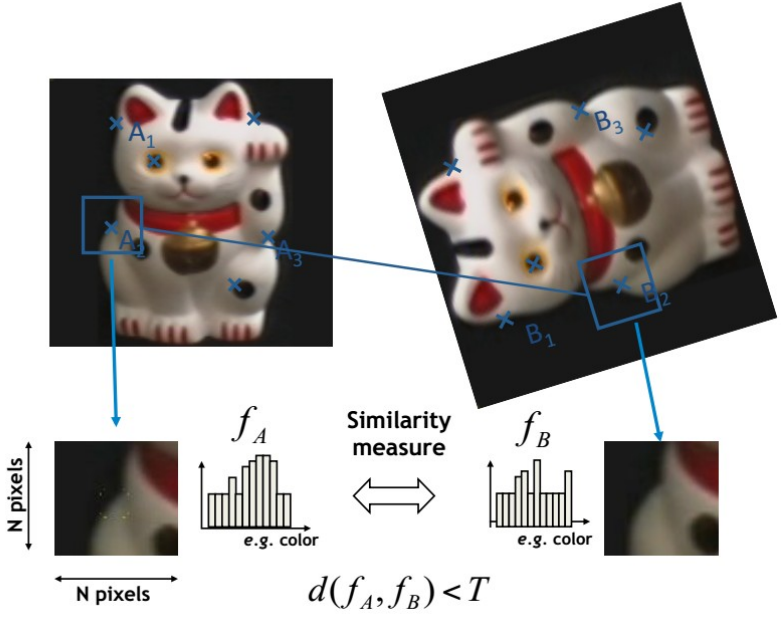
UNIVERSITÀ DI PARMA

- **Repeatability:** to be able to find the same features on even very different images
- **Saliency:** the feature contains information
- **Locality:** relatively small area of the image, namely more robust wrt occlusions and clutter

Example recap

UNIVERSITÀ DI PARMA

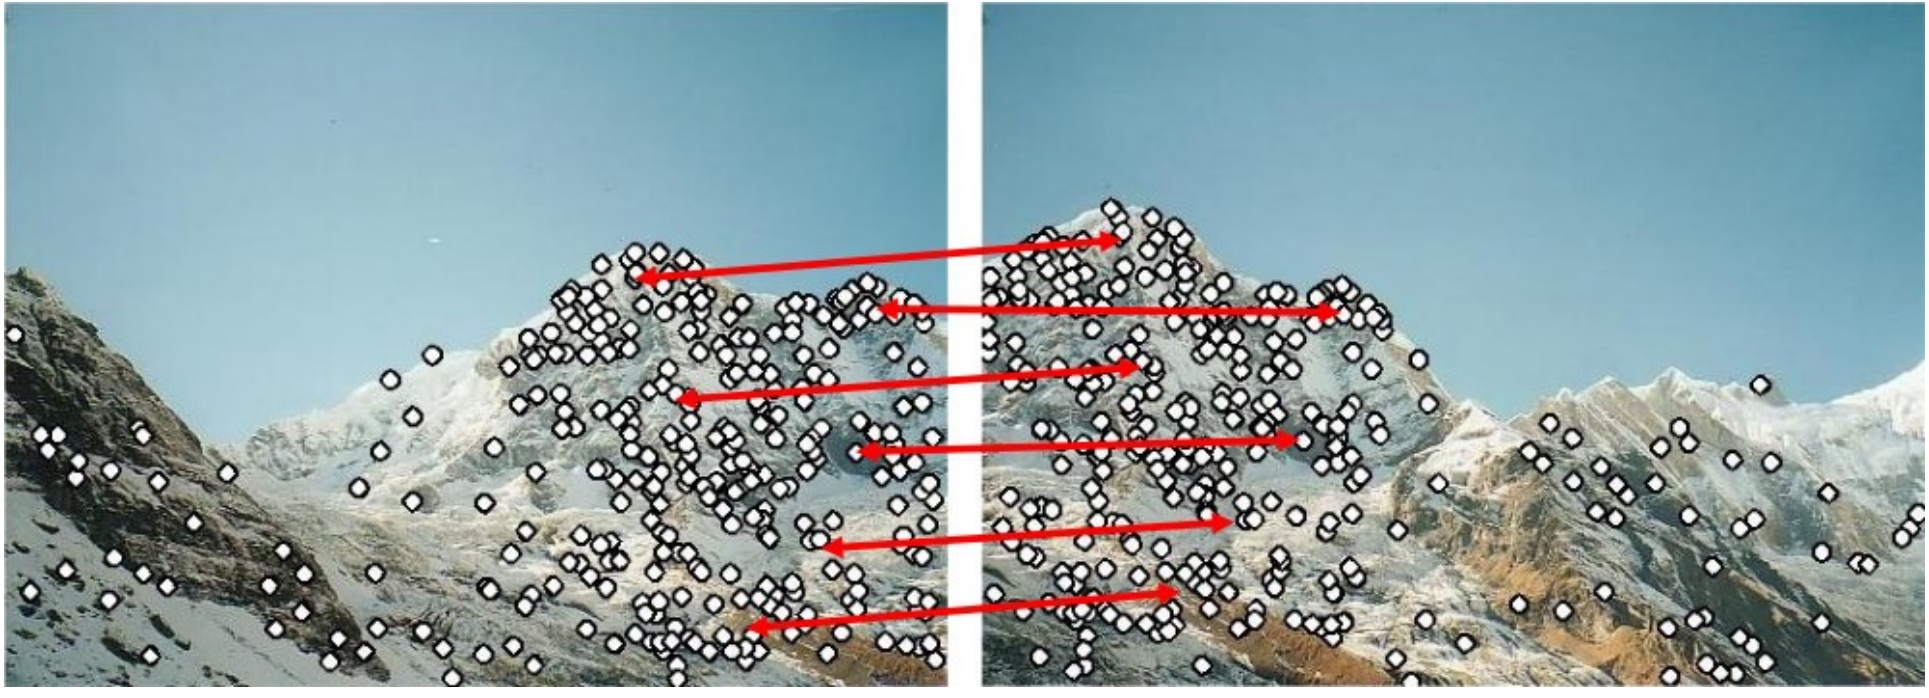
- Select specific points ⟶ keypoints or features ⟶ **features extraction**
- Find potential correspondences ⟶ **features matching**
- Application dependent step
  - Matching
  - Indexing
  - Detection
  - Image alignement



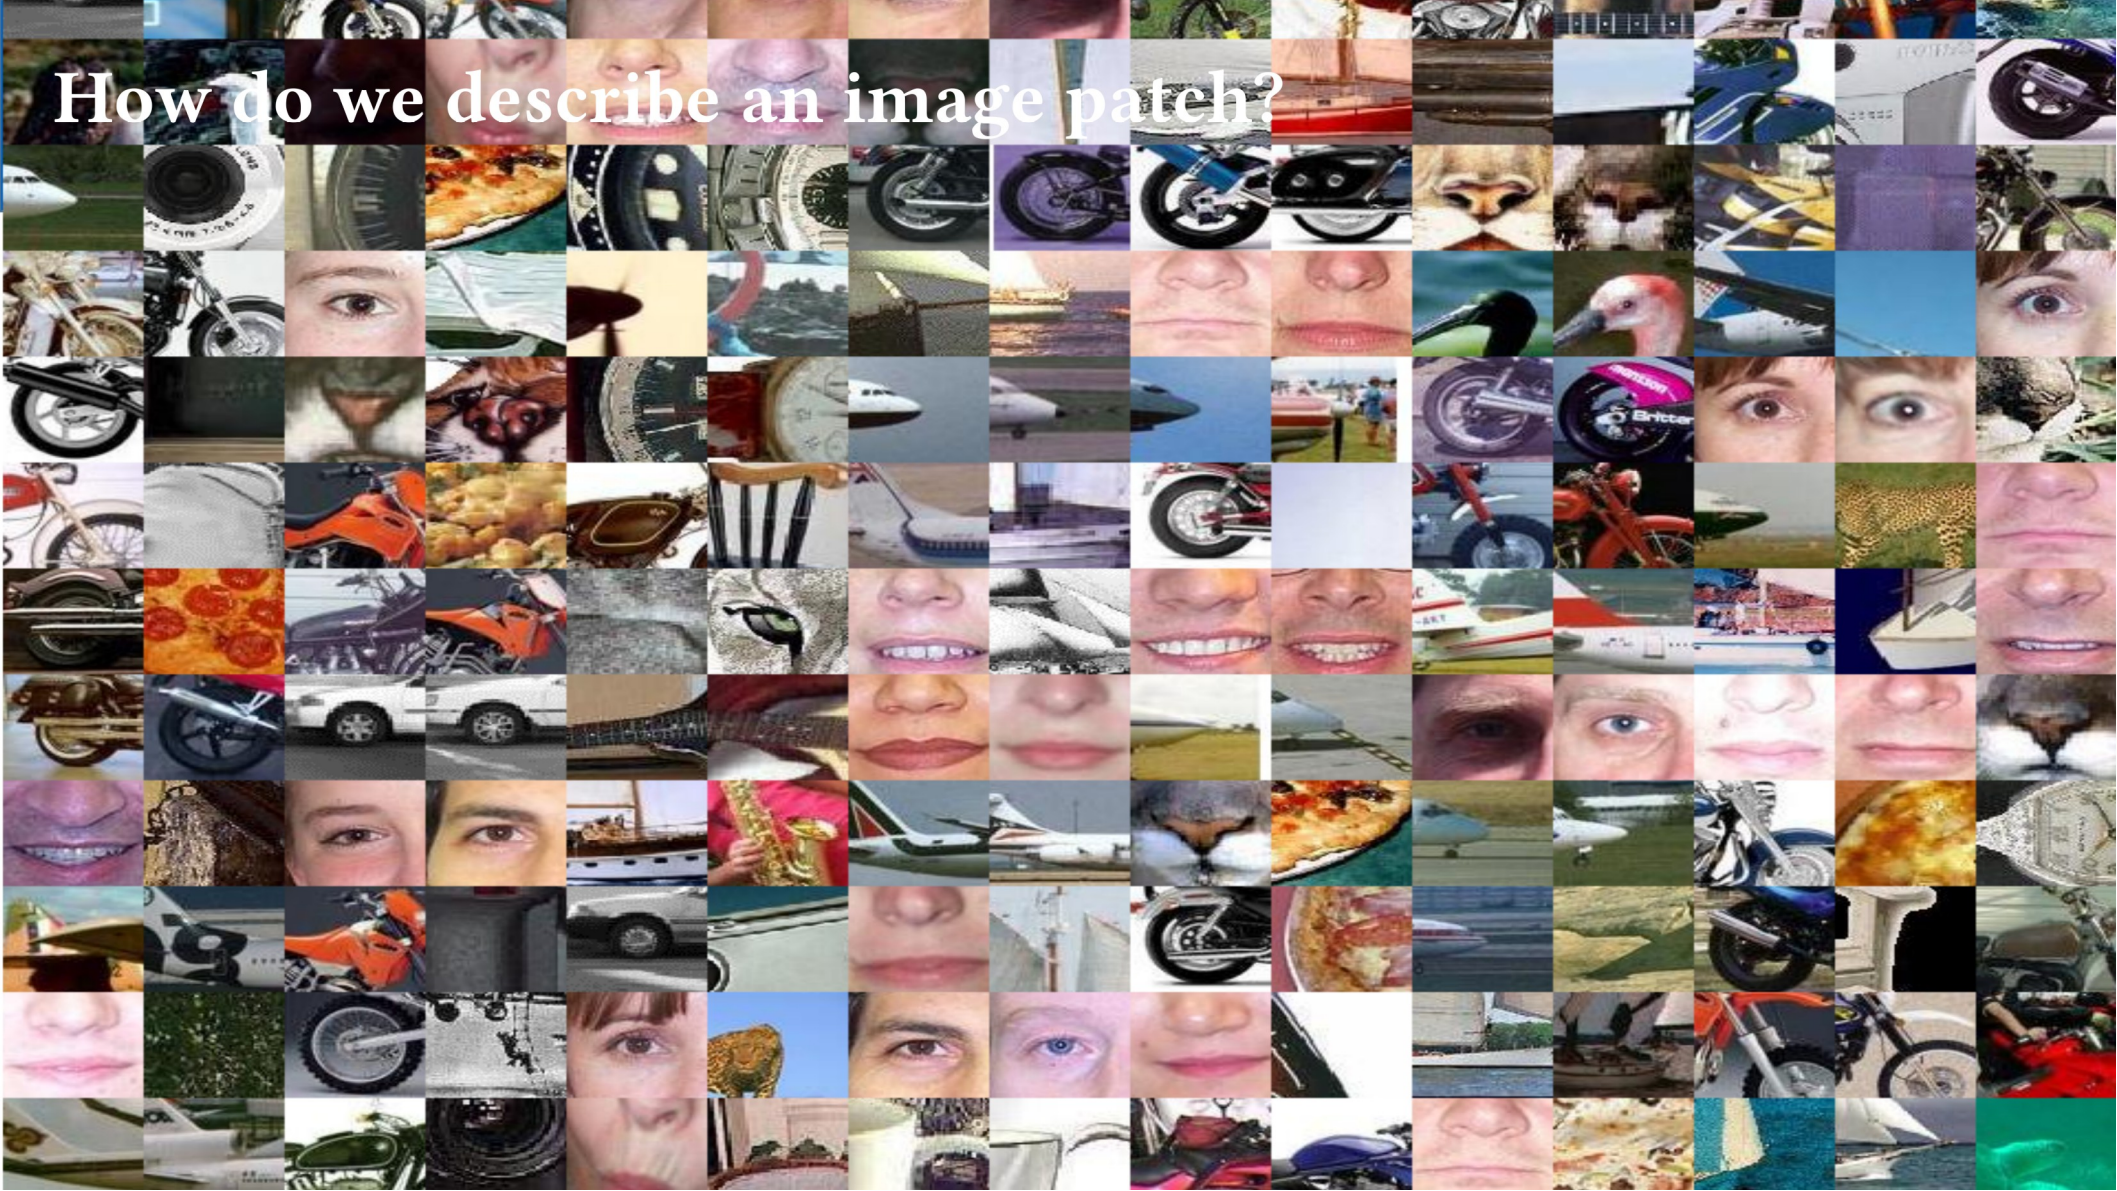
Example

UNIVERSITÀ DI PARMA

- How to describe keypoints for matching?
  - Keypoints themselves does not work ⟶ feature descriptor



How do we describe an image patch?

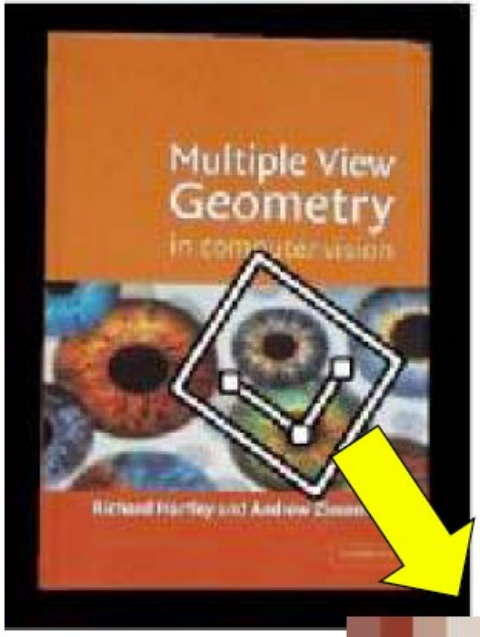


Feature descriptor

UNIVERSITÀ DI PARMA

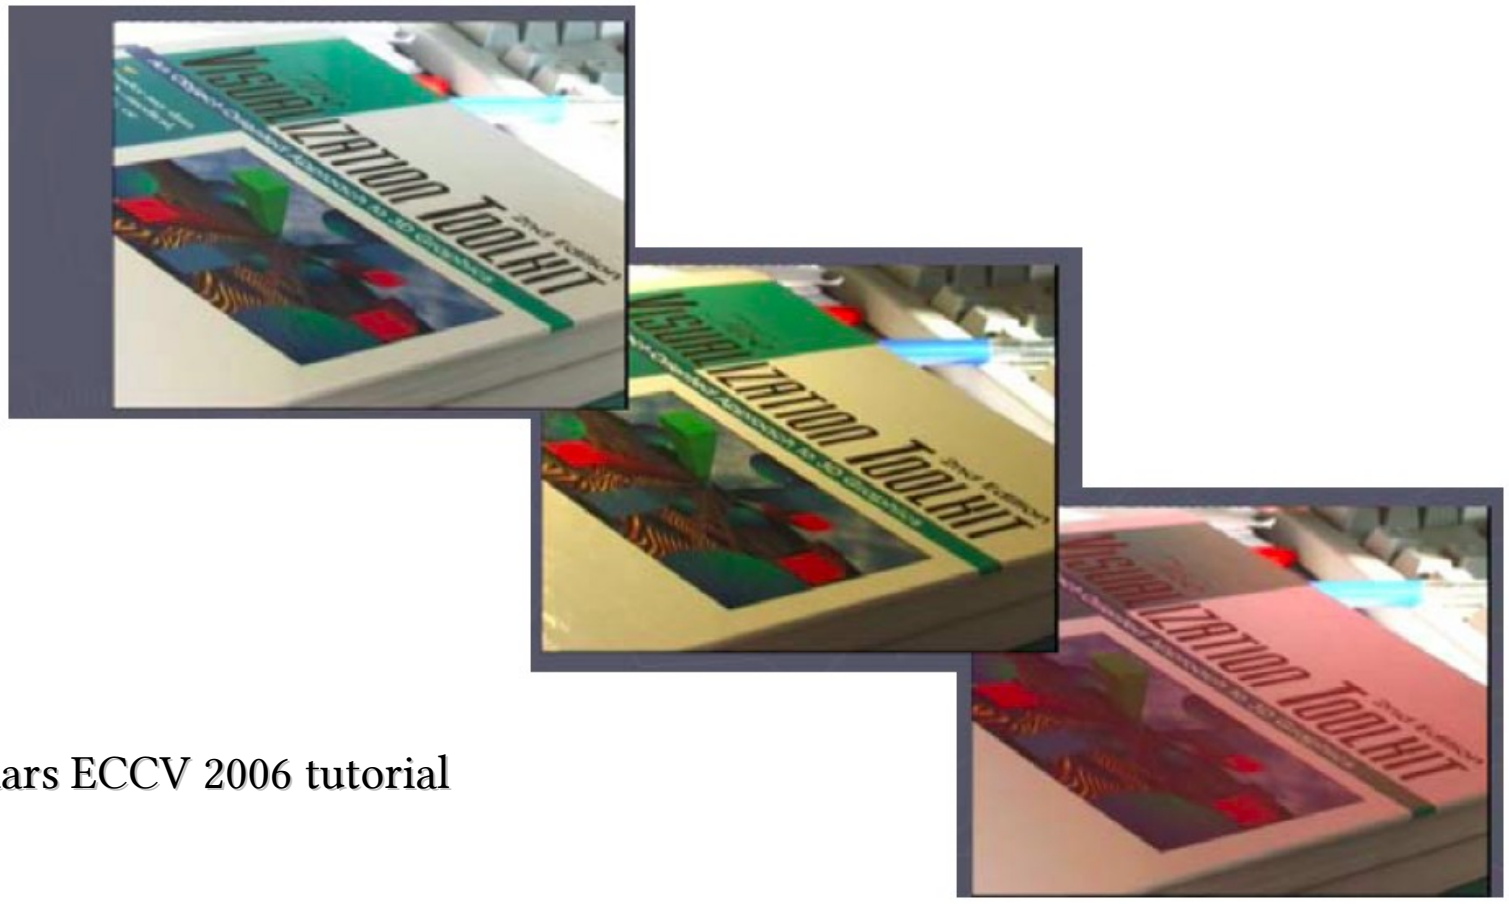
- Match should be as much as unique as possible
- Issues
  - Geometrical transformations
    - Translation
    - Scale
    - Rotation
    - …
  - Photometrical transofrmations
    - Illuminations
    - Color
    - …

Orientation, scale (and translation)



e.g. scale, translation, rotation

Illumination & color



T. Tuytelaars ECCV 2006 tutorial

Feature descriptor

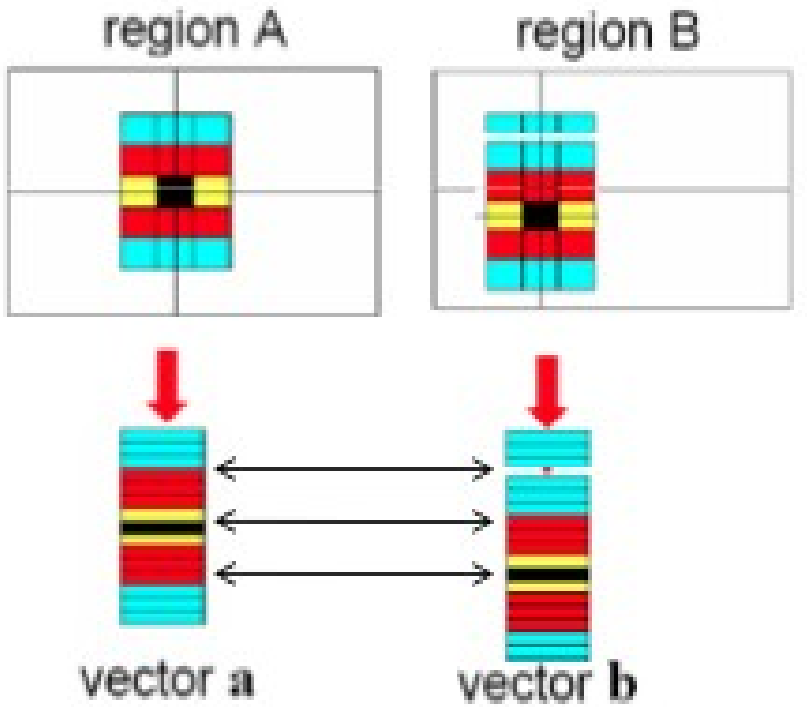
UNIVERSITÀ DI PARMA

- To match patches we do not use patches themselves
- What is a keypoint descriptor?
  - Keypoint “measure” that can be effectively used for matching
- Properties
  - Invariant/Robust
  - Distinctive
  - Compact
  - Efficient

Raw Patches

UNIVERSITÀ DI PARMA

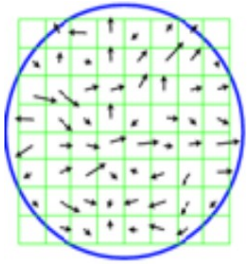
- Create a feature vector, and normalize it
  - Normalization for mean and variance reduce matching problems
- Very sensitive to even small shifts, rotations and any affine transformation

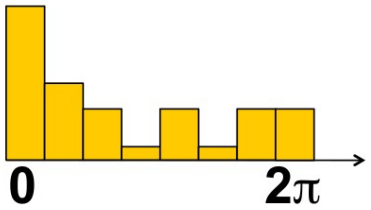


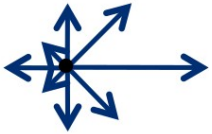
Rotation invariance

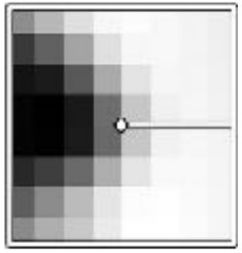
UNIVERSITÀ DI PARMA

- Compute gradients and a histogram of gradients
  - Rotate the patch according to dominant maxima or average









Scale invariance

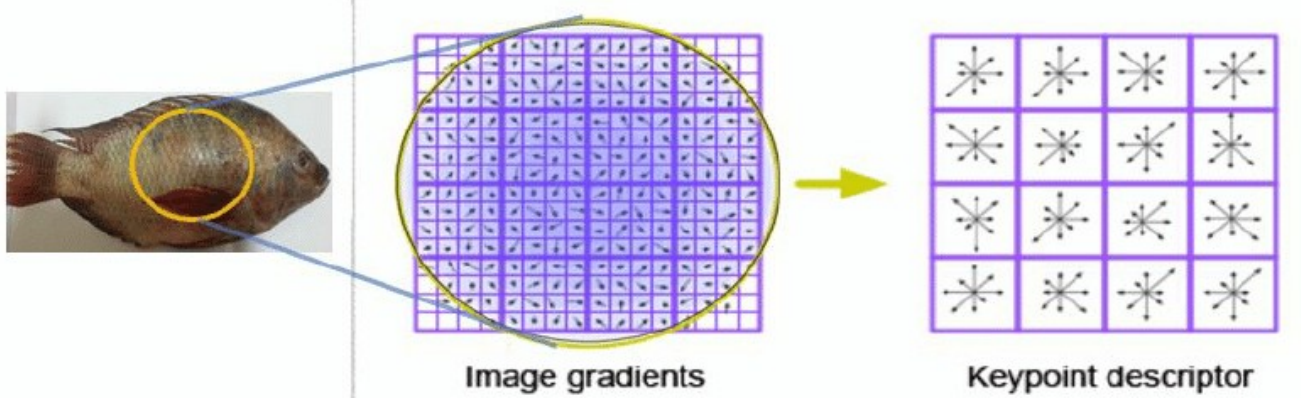
UNIVERSITÀ DI PARMA

- For Harris keypoints we used a pyramidal approach
  - i.e. a multiscale window

SIFT – Scale Invariant Feature Transform

UNIVERSITÀ DI PARMA

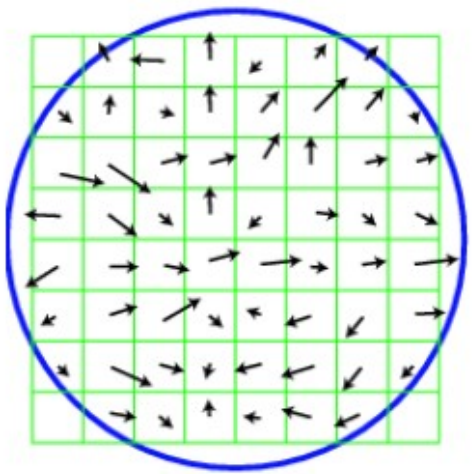
- Lowe 2004
  - Also keypoints extraction
- Robust wrt geometric transformations
  - Scale and Rotation
- Anyway robust wrt luminance variations
- Unfortunately slow



SIFT – Scale Invariant Feature Transform

UNIVERSITÀ DI PARMA

- For each keypoint
  - Compute gradient in a specific window around the keypoint
  - Gradient is also downweight using a Gaussian filtering



SIFT – Scale Invariant Feature Transform

UNIVERSITÀ DI PARMA

- For each keypoint
  - Compute gradient in a specific window around the keypoint
  - Gradient is also downweight using a Gaussian filtering

$$L(x, y, \sigma) = G(x, y, \sigma) * I(x, y)$$

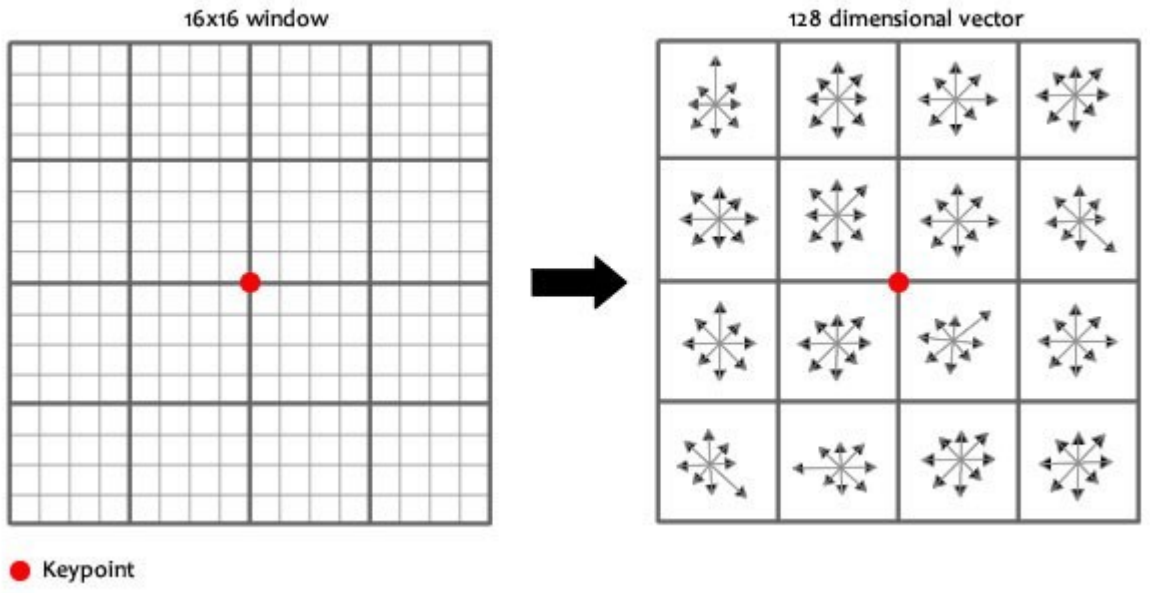
$$m(x, y) = \sqrt{(L(x+1, y) - L(x-1, y))^2 + (L(x, y+1) - L(x, y-1))^2}$$

$$\theta(x, y) = \tan^{-1}((L(x, y+1) - L(x, y-1))/(L(x+1, y) - L(x-1, y)))$$

SIFT – Scale Invariant Feature Transform

UNIVERSITÀ DI PARMA

- In the gradient window:
  - Compute a gradient orientation in the 4×4 quadrant



SIFT – Scale Invariant Feature Transform

example 8x8 locations 2x2 histogram array

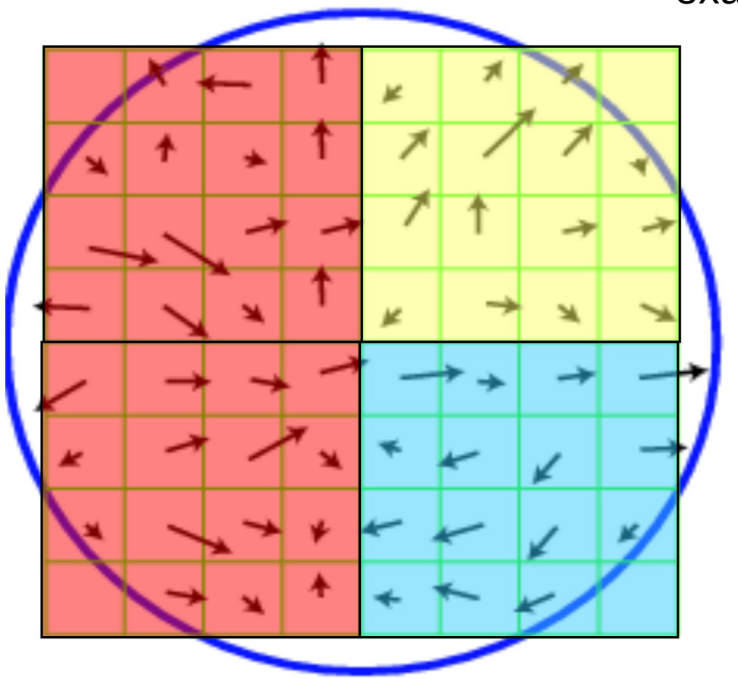


Image gradients

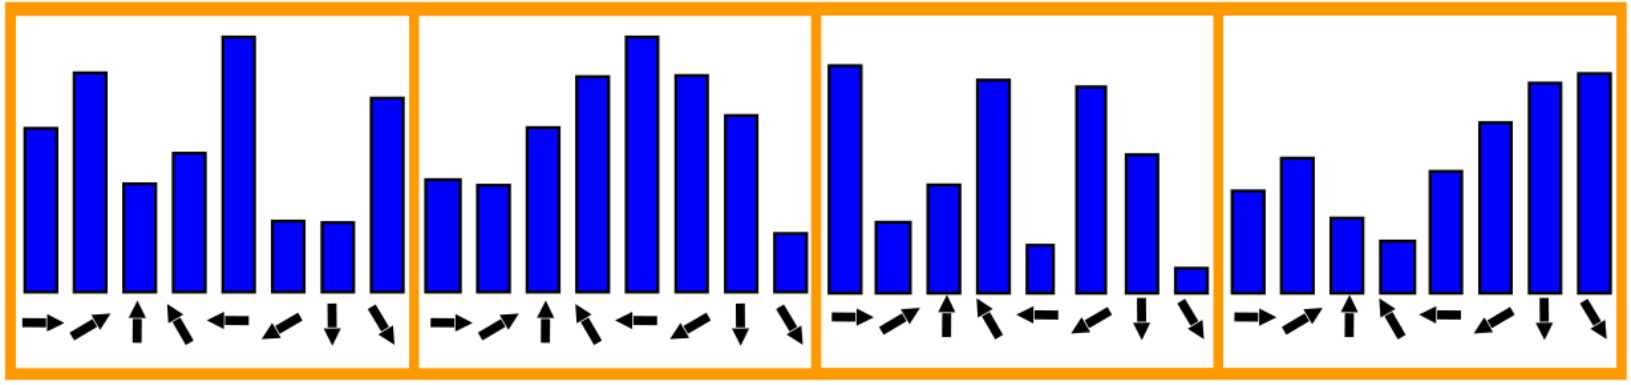
Keypoint descriptor

SIFT – Scale Invariant Feature Transform

UNIVERSITÀ DI PARMA

- In the gradient window:
  - Compute a gradient orientation in each 4×4 quadrant
  - Accumulate results in histogram bins (8 in the figure)



SIFT – Scale Invariant Feature Transform

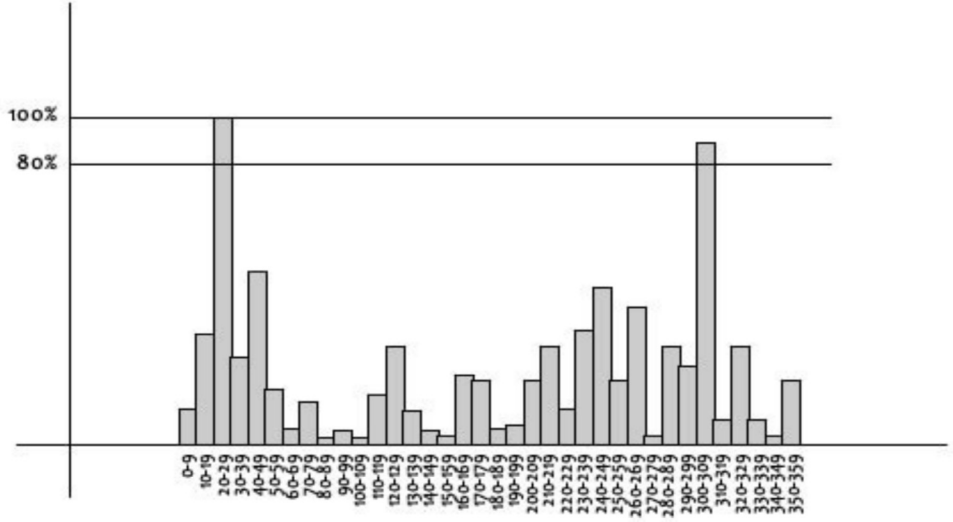
UNIVERSITÀ DI PARMA

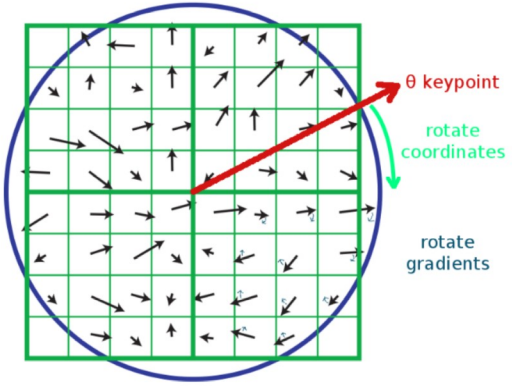
- We showed different situations!
  - Where is the truth?
- Assume that we bin "o" orientations over "$k \times k$" quadrants, where each quadrant is "$s \times s$" pixels
- What's final dimensionality of descriptor?
  - Common implementation: o=8, k=4, s=4 ⟶ 128

SIFT – Scale Invariant Feature Transform

UNIVERSITÀ DI PARMA

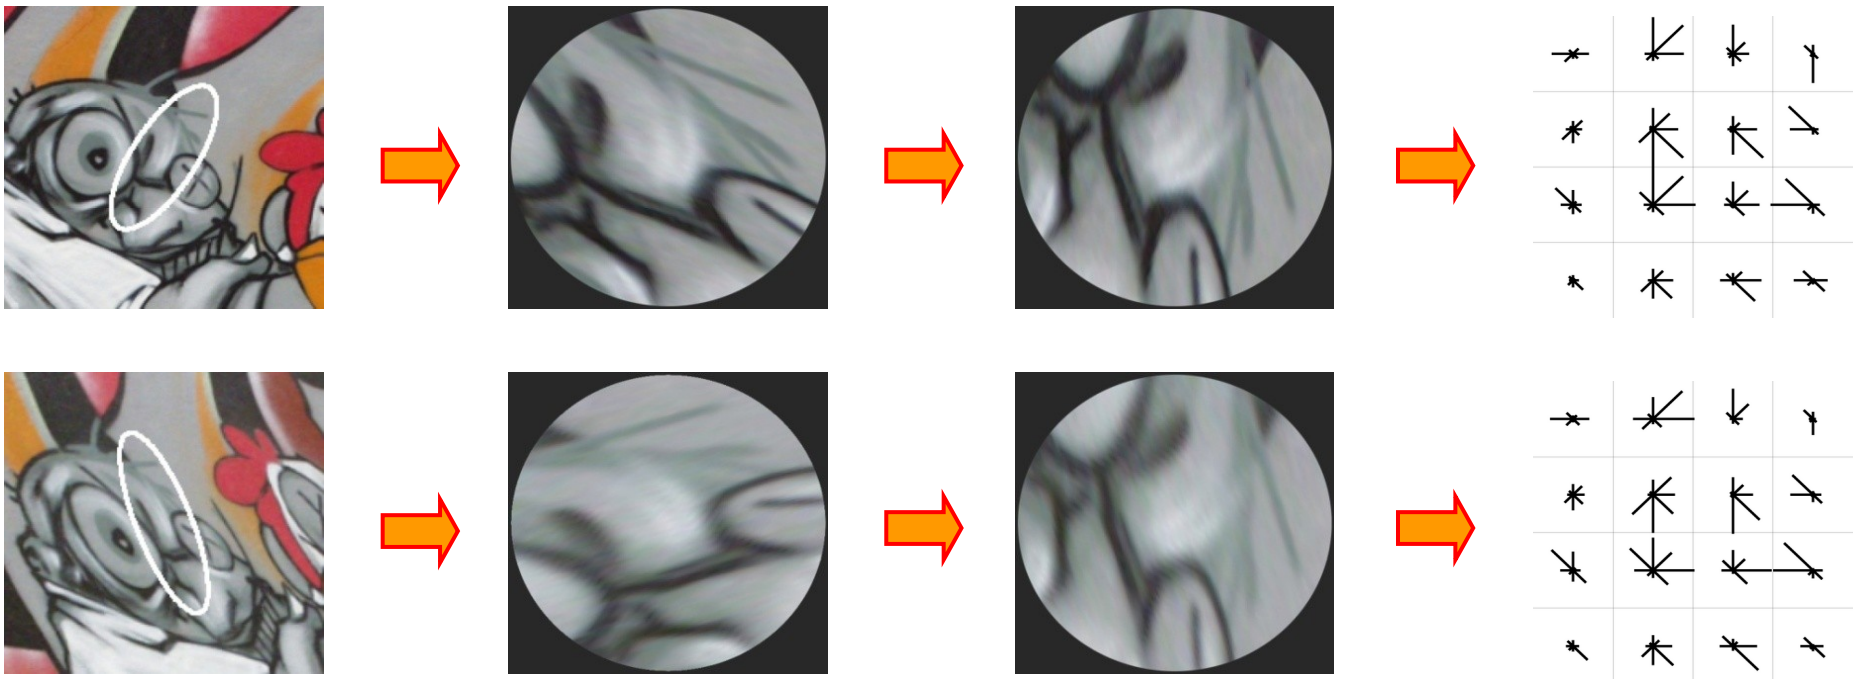
- Maximum gaves us info about keypoint orientation
  - Optionally we also consider other potential orientation when we have other values close to maximum
    - Namely we can have more than one descriptor





SIFT – Scale Invariant Feature Transform

UNIVERSITÀ DI PARMA



SIFT – Scale Invariant Feature Transform

UNIVERSITÀ DI PARMA

- How to obtain invariance wrt contrast?
  - Rescale to have unit norm $\rightarrow$ $x = \frac{x}{\|x\|} \quad x \in \mathbb{R}^{128}$
- How to obtain invariance wrt luminance?
  - Do you remember we used gradients?
  - Anyway values are “clipped” to 0.2 to improve robustness to photometric variations
- How to obtain invariance wrt rotation?
  - We used the whole patch orientation to adjust x

SIFT – Scale Invariant Feature Transform

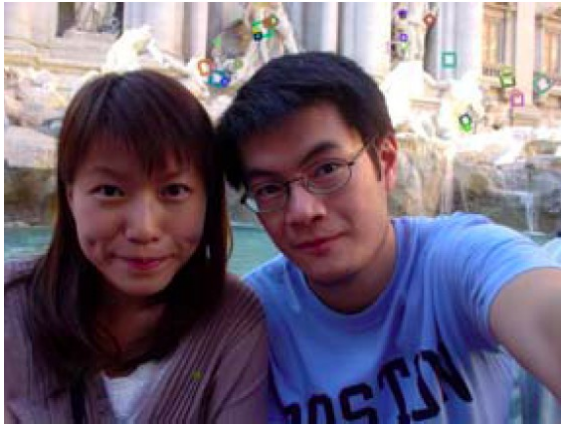
UNIVERSITÀ DI PARMA

- Result is then a 128 dim vector
  - Float values
- How to match them?
  - Euclidean distance can be effectively used
- See OpenCV example

SIFT – Scale Invariant Feature Transform

UNIVERSITÀ DI PARMA

- Summary
  - Extraordinarly robust matching technique
  - Sometimes matches night vs day
  - Lots of code available

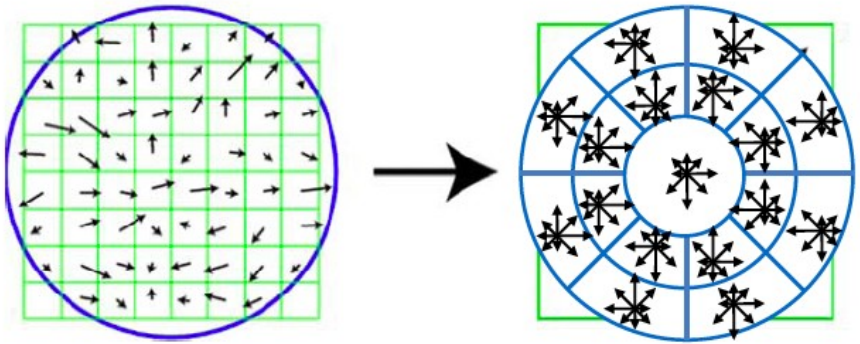


PCA SIFT

- Principal Component Analysis
  - Reduce the dimensionality of a data set
  - From 128 to 10 or so
  - A linear transformation (eigendecomposition) is used to extract principal components
  - Needs training!

GLOH

- Gradient location-orientation histogram
  - Uses a log-polar binning structure instead of quadrants.
  - Exploits 17 spatial bins and 16 orientation bins.
  - PCA (trained on a large dataset) is used to reduce the 272 space to a 128 one



(a) image gradients (b) keypoint descriptor

SURF

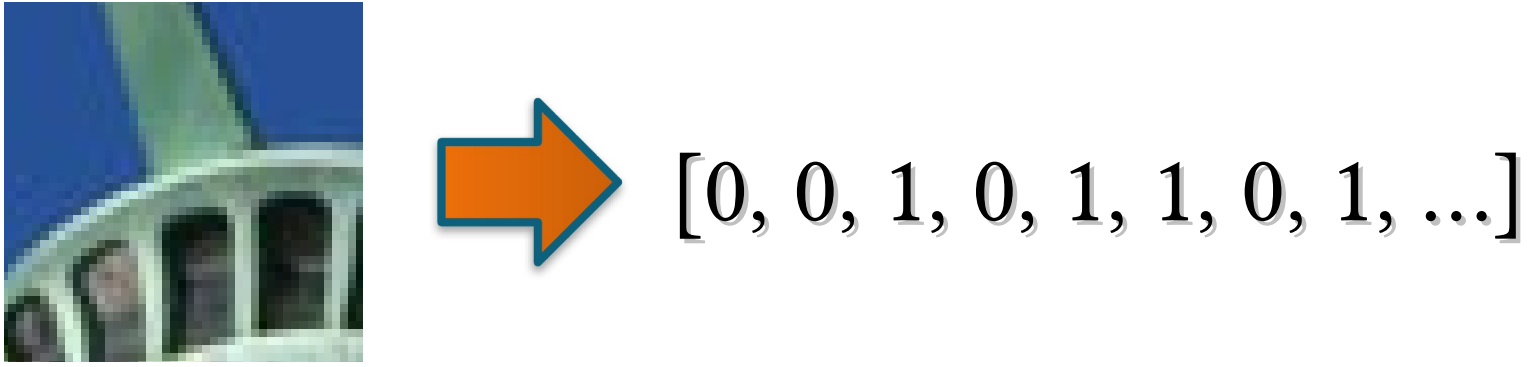
- Speeded Up Robust Feature
  - Again similar to SIFT
  - 20×20 patch subdivided in 4×4 quadrants
  - 64D descriptor
  - As stable as SIFT but several times faster than SIFT

Both SIFT and SURF are patented algorithms!

Binary Descriptors

UNIVERSITÀ DI PARMA

- Using SIFT, SURF… we obtain “floating point” values
  - Match have to cope with this
  - Binary values can be faster to be matched



Binary Descriptors

UNIVERSITÀ DI PARMA

- BRIEF
  - Binary Robust Independent Elementary Features
- FREAK
  - Fast Retina Keypoint
- BRISK
  - Binary Robust Invariant Scalable Keypoints
- ORB
  - Oriented FAST and Rotated BRIEF

BRIEF

- After a gaussian smoothing of patch, several intensity comparisons between pair of pixels are performed
- Each pair is selected according to a specific pattern
  - Anyway the same pattern is used for all patches

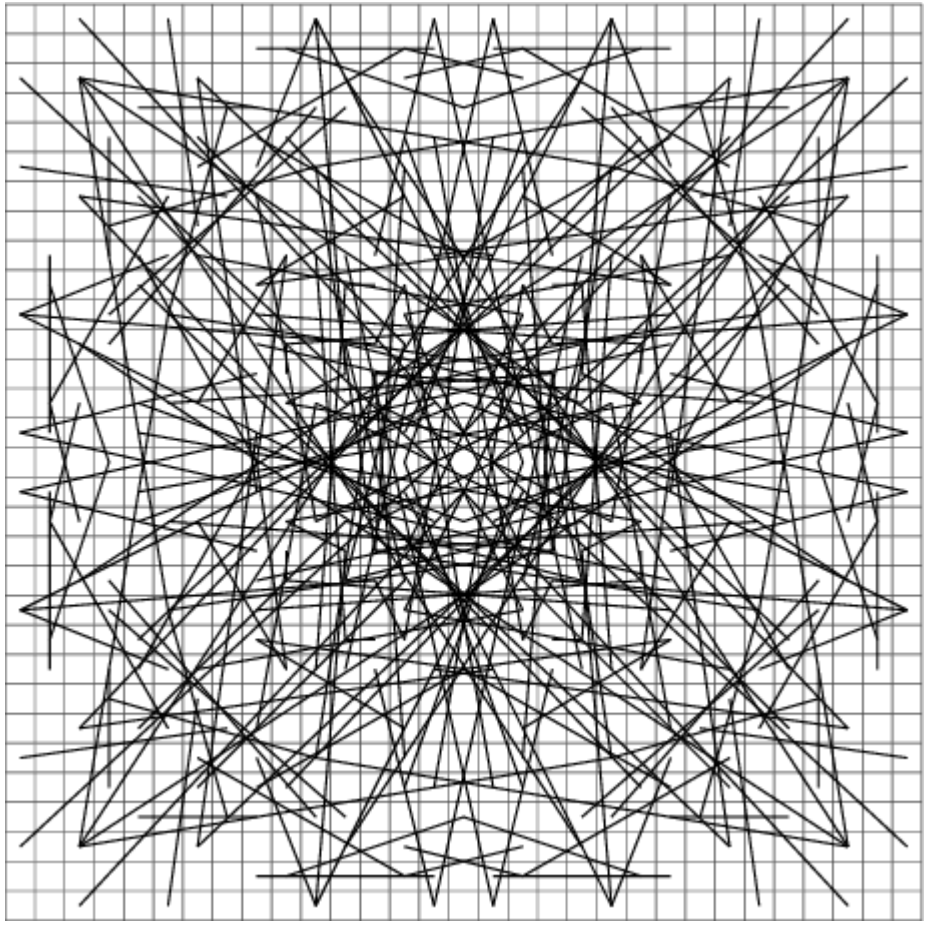
Binary test

$$\tau(p; x, y) := \begin{cases} 1 & if\ p(x) < p(y) \\ 0 & otherwise \end{cases}$$

BRIEF descriptor

$$f_{n_d}(p) := \sum_{1 \le i \le n_d} 2^{i-1} \tau(p; x_i, y_j)$$

BRIEF: pattern example

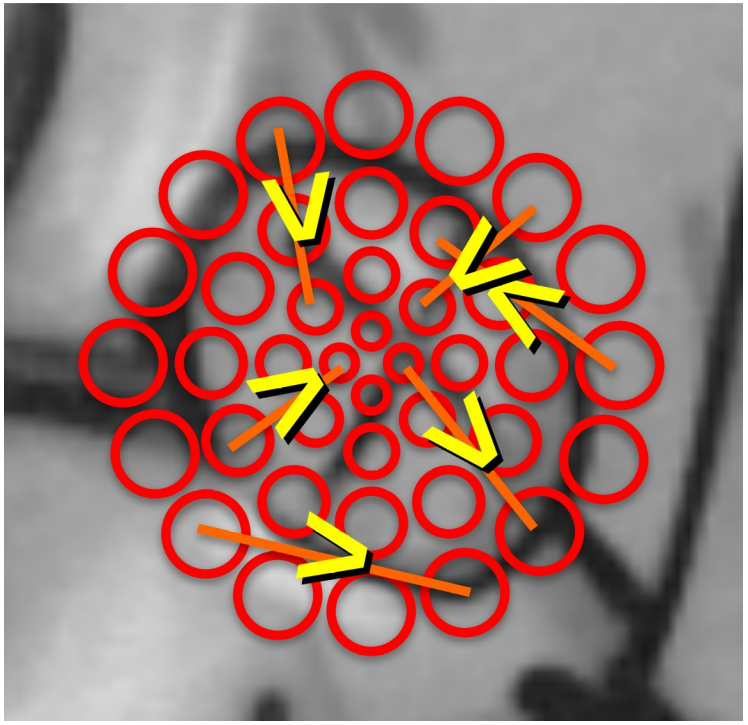


- Different strategies for sampling geometry
  - Random
  - Uniform: random pairs having anyway a fixed distance
  - Gaussian: gaussian distributions around the keypoint
  - Gaussian 2: first point selected as previous strategy, but second one as gaussian distribution centered on the former
  - Polar: simmetry wrt keypoint

BRIEF

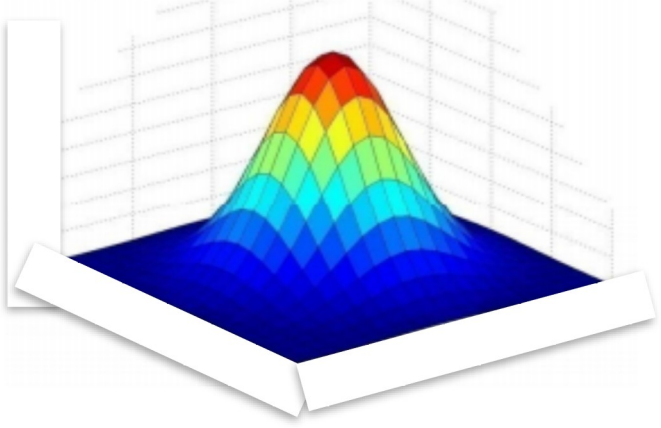
- Pro
  - Simple intensity comparison
  - Definitely fast
  - Good results
- Cons
  - Not very reliable against rotations
- Solution $\longrightarrow$ ORB
  - Oriented FAST and rotated BRIEF

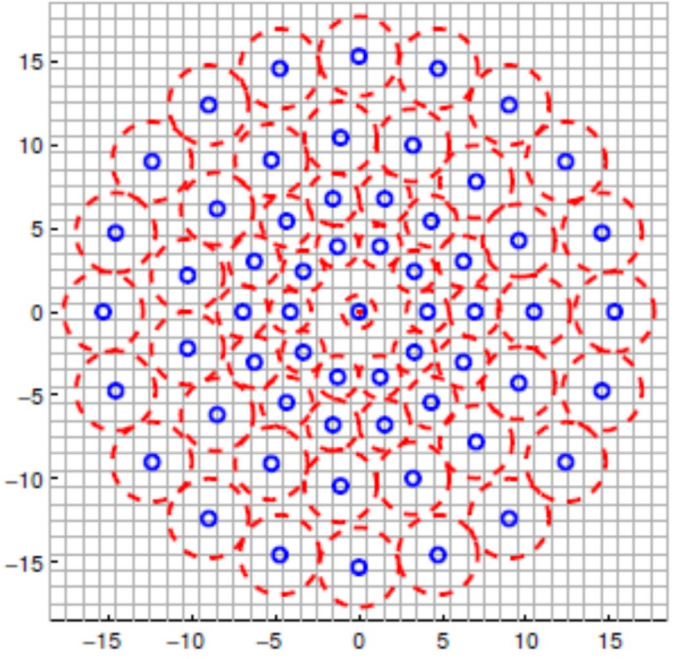
- Binary Robust Scalable Keypoints



- Same approach as BRIEF but given pattern

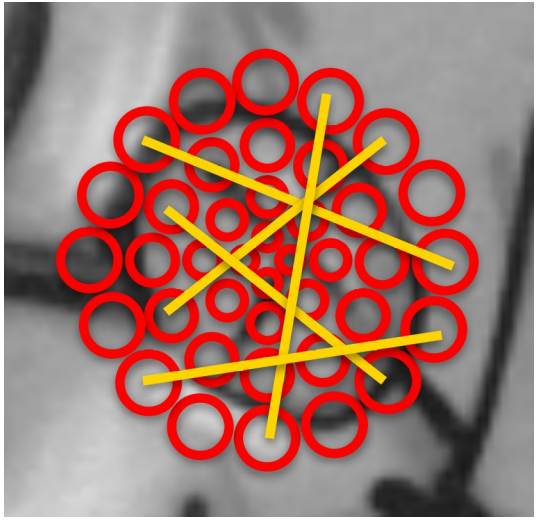
2D Gaussian around each sampling point





BRISK

- A number of sampling pairs is selected
- For each pair the gradient is computed betwwen the 2 smoothed intensity
- Different pairs are used for computing descriptor and patch orientation



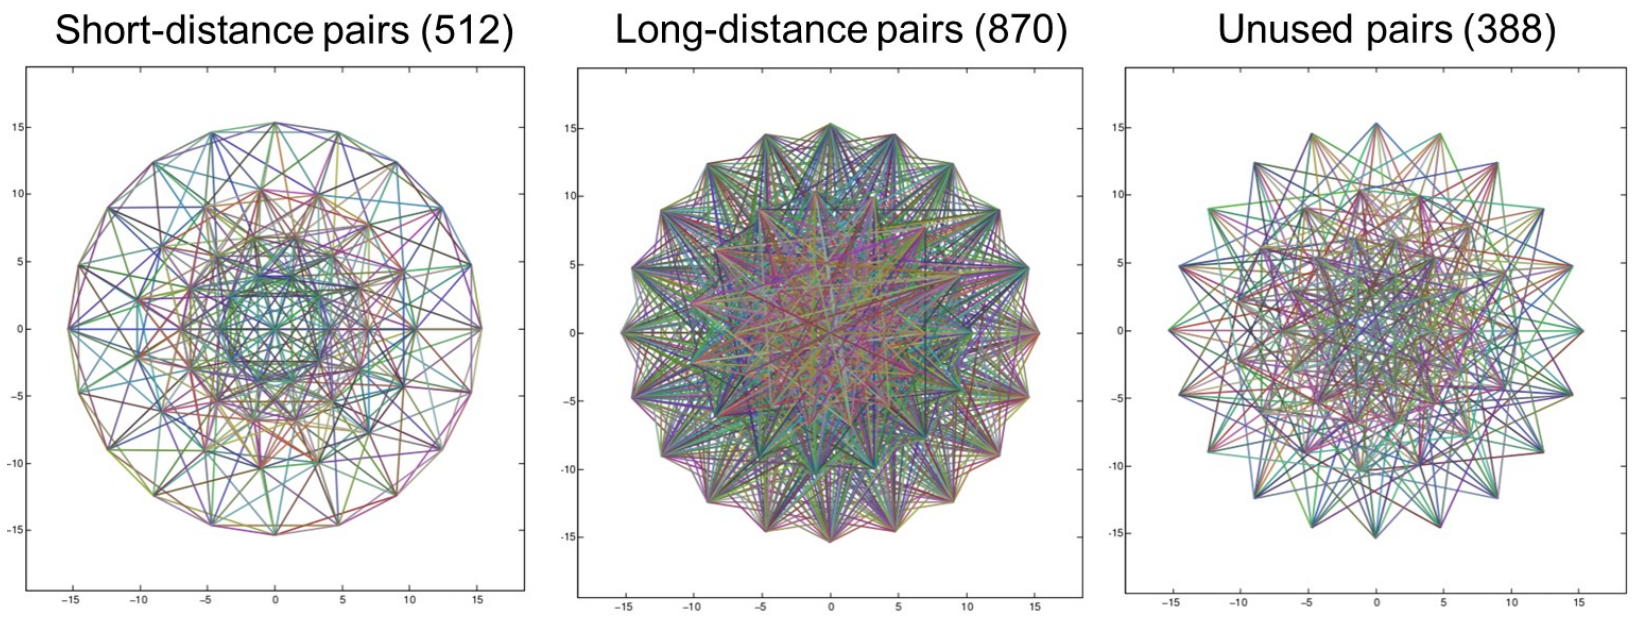
$$\mathbf{g}(\mathbf{p}_i,\mathbf{p}_j)=\underbrace{\frac{(\mathbf{p}_j-\mathbf{p}_i)}{\|\mathbf{p}_j-\mathbf{p}_i\|}}_{\text{unit vector}}\cdot\underbrace{\frac{I(\mathbf{p}_j,\sigma_j)-I(\mathbf{p}_i,\sigma_i)}{\|\mathbf{p}_j-\mathbf{p}_i\|}}_{\text{gradient magnitude}}$$

$$g=\begin{pmatrix}g_x\\g_y\end{pmatrix}=\frac{1}{L}\sum_{p_i,p_j\in L}g(p_i,p_j)$$

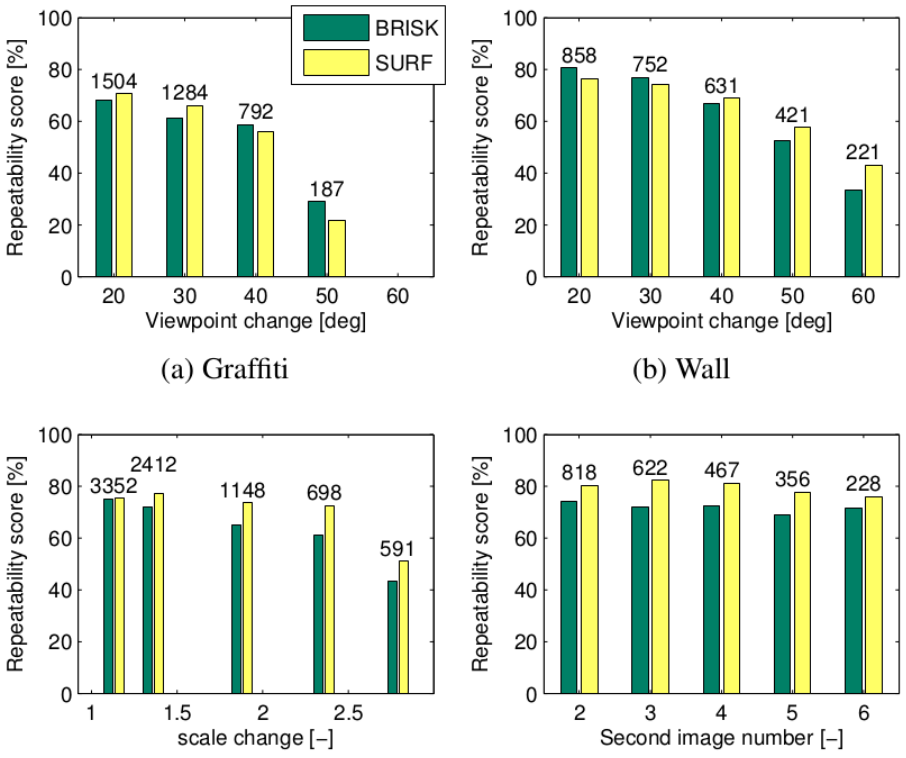
BRISK

UNIVERSITÀ DI PARMA

- Short distance pairs → descriptor → $I(p_j,\sigma_j) > I(p_i,\sigma_i)$
- Long distance pairs → orientation → $\arctan2(g_y,g_x)$



BRISK Repeatability



(a) Graffiti (b) Wall

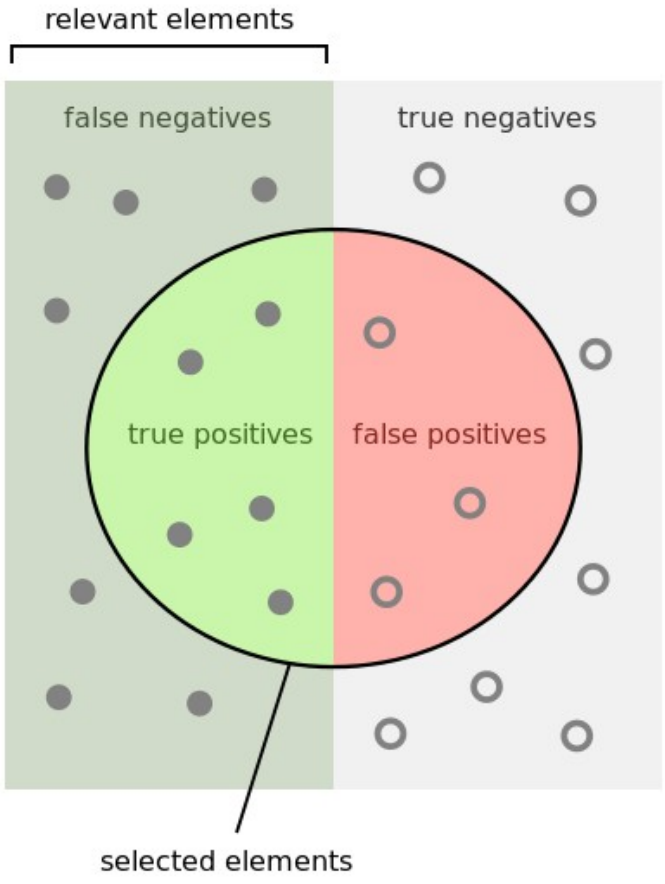
(c) Boat (d) Leuven

Figure 5. Repeatability scores for 50% overlap error of the BRISK and the SURF detector. The resulting similarity correspondences (approximately matched between the detectors) are given as numbers above the bars.

(a) Graffiti (b) Wall (c) Boat

Leuven

Precision-Recall



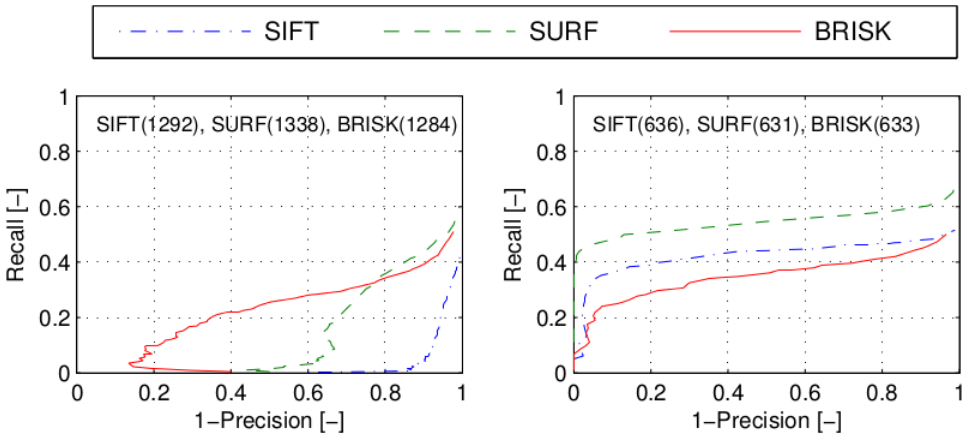
How many selected items are relevant?

$$\text{Precision} = \frac{\text{true positives}}{\text{selected elements}}$$

How many relevant items are selected?

$$\text{Recall} = \frac{\text{true positives}}{\text{relevant elements}}$$

Overall Algorithm Results



(a) Graffiti 1-3

(h) Ubc 1-4

Timings

UNIVERSITÀ DI PARMA

- Scalable for faster execution by
  - Reducing number of sampling pairs
  - Examining only one scale
  - Omitting pattern rotation step

	SIFT	SURF	BRISK
Detection threshold	4.4	45700	67
Number of points	1851	1557	1051
Detection time [ms]	1611	107.9	17.20
Description time [ms]	9784	559.1	22.08
Total time [ms]	11395	667.0	39.28
Time per point (ms)	**6.156**	**0.4284**	**0.03737**

Table 1. Detection and extraction timings for the first image in the Graffiti sequence (size: 800 × 640 pixels).

	SIFT	SURF	BRISK
Points in first image	1851	1557	1051
Points in second image	2347	1888	1385
Total time [ms]	291.6	194.6	29.92
Time per comparison [ns]	**67.12**	**66.20**	**20.55**

BRISK

Binary Robust Invariant Scalable Keypoints

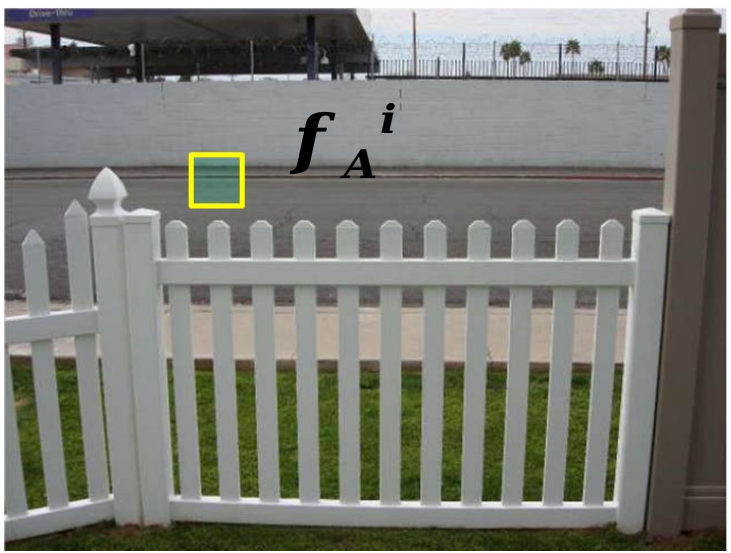
Stefan Leutenegger, Margarita Chli and Roland Siegwart

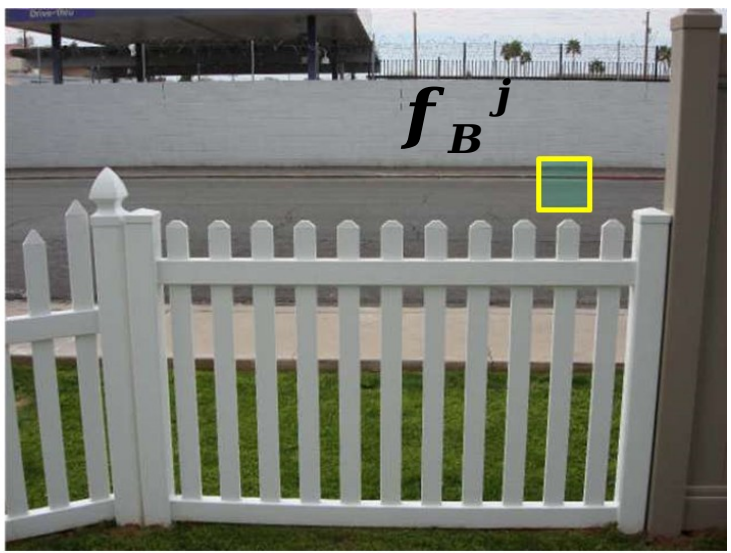
ICCV 2011

Matching

UNIVERSITÀ DI PARMA

- We found keypoints
- We compute descriptors
- And now?





Matching

UNIVERSITÀ DI PARMA

- For each descriptor i of image A
  - Measure “distance” with each descriptor j of image B
  - Get the two best matches
  - Compare them against a threshold
    - Above ⟶ no match
    - Below ⟶ compute the ratio distance

$$\frac{dist\left(f_A^i, f_B^{best}\right)}{dist\left(f_A^i, f_B^{2^{nd}\,best}\right)}$$

Matching

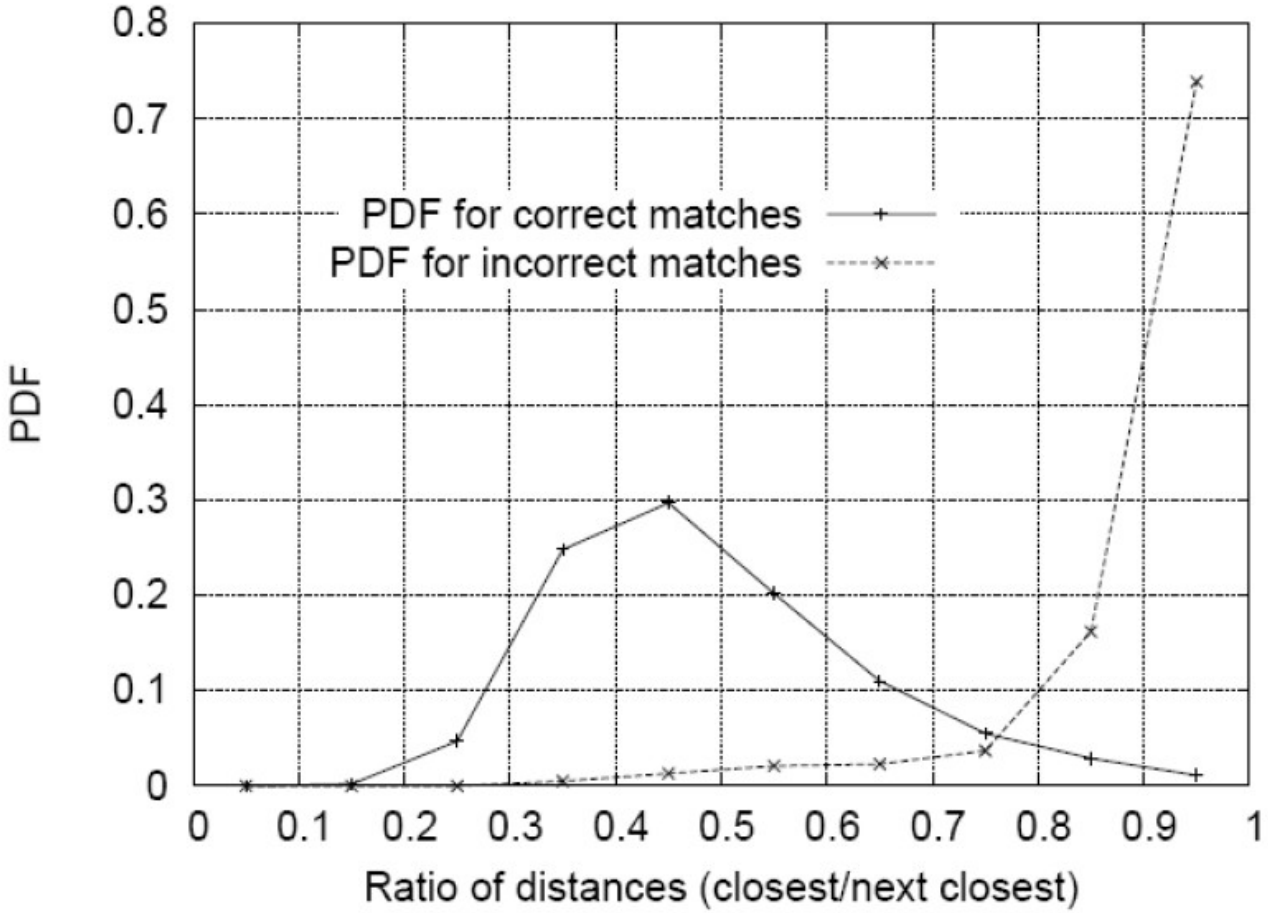
UNIVERSITÀ DI PARMA

- When ratio distance ~ 1 ⟶ no match
  - Matches are too similar ⟶ ambiguity
- When ratio distance >> 1 ⟶ we have a match
  - First match outperforms 2nd one (and others)

$$\frac{dist\left(f_A^i, f_B^{best}\right)}{dist\left(f_A^i, f_B^{2^{nd}\,best}\right)}$$

Matching (Probability Density Function)

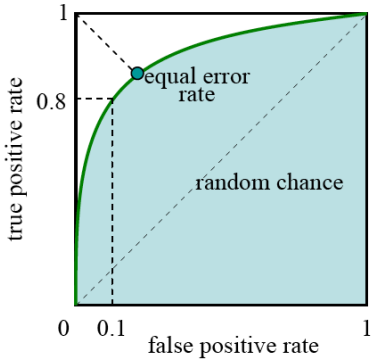
UNIVERSITÀ DI PARMA



Matching

UNIVERSITÀ DI PARMA

- Other thresholdes have to be selected, how?
  - precision/recall analysis
  - empirically



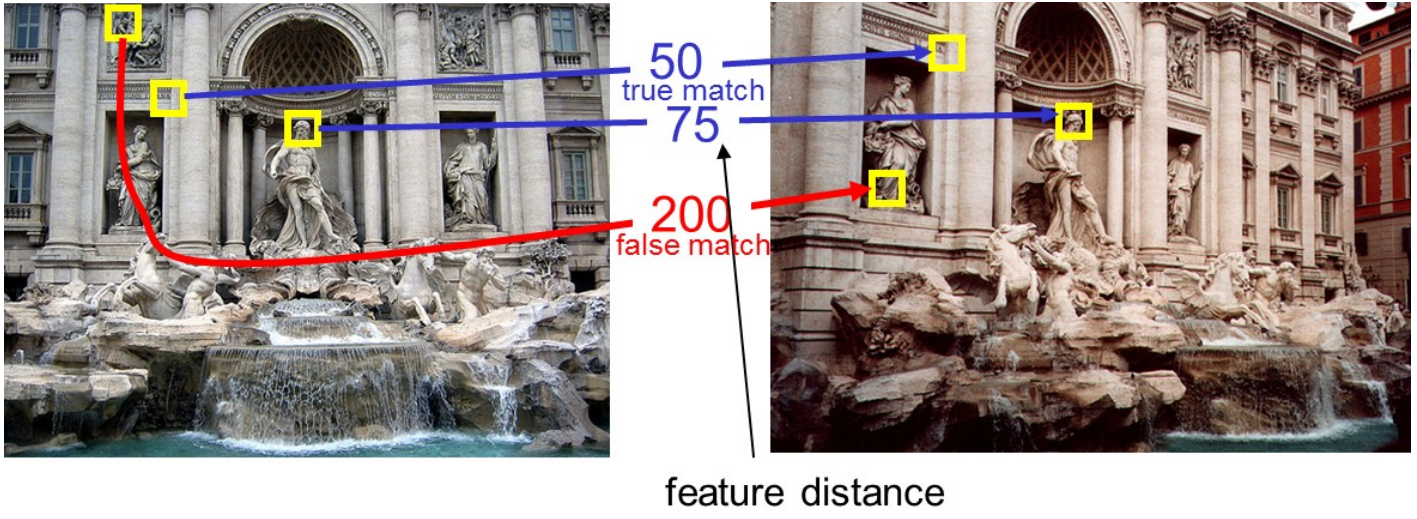


Image Stitching

UNIVERSITÀ DI PARMA

- Combine multiple images in a single view

Image Stitching

UNIVERSITÀ DI PARMA

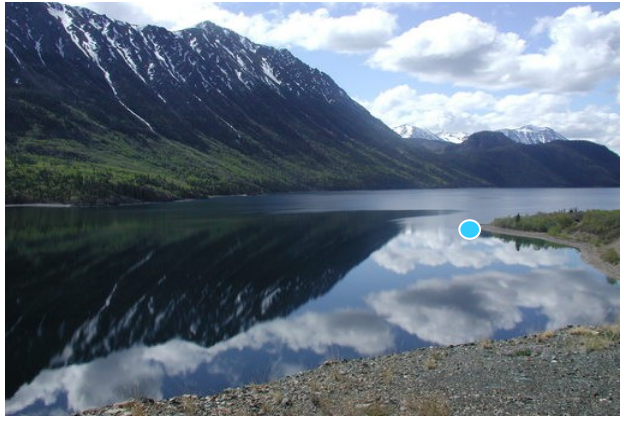
- Main steps
  - Acquire multiple images
  - Get transformation from first image to following one
  - Reproject that image onto the previous one
  - Blend them in the result
  - Until we have images $\longrightarrow$ repeat

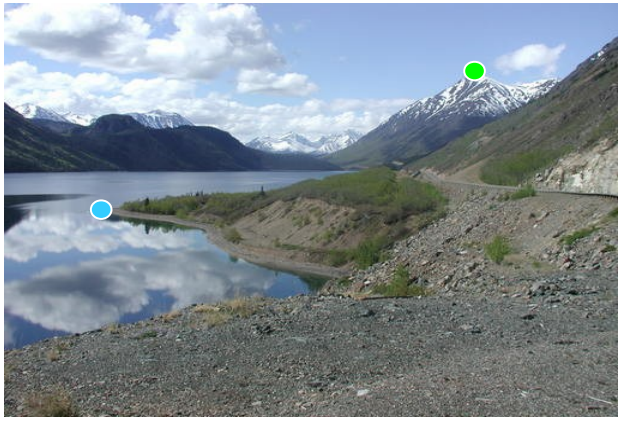
Image Stitching

UNIVERSITÀ DI PARMA

- Main steps
  - Acquire multiple images
  - Get transformation from first image to following one
  - Reproject that image onto the previous one
  - Blend them in the result
  - Until we have images ⟶ repeat

Image Stitching





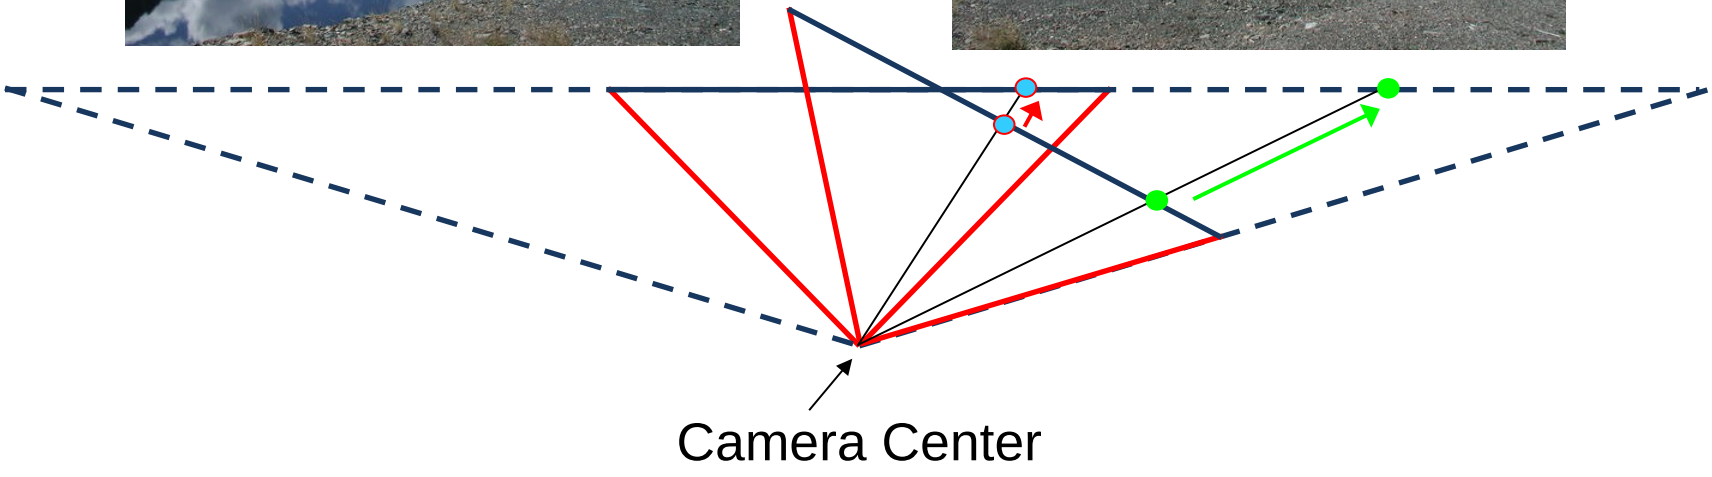


Image Stitching

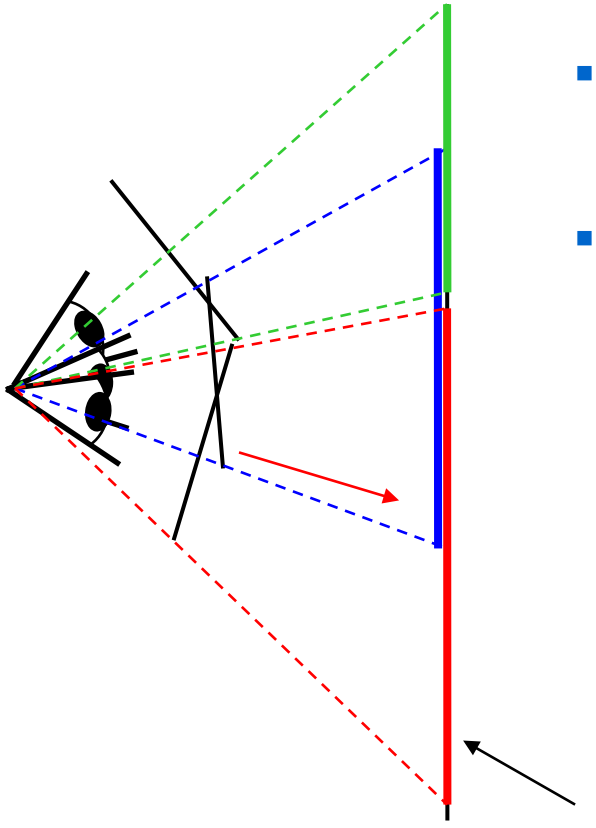


- Reproject images on a common plane
- We have a “virtual” camera that correspondcs to that plane with a FOV sufficiently large to include all other views

Homography

- The relation under a projection is an homography

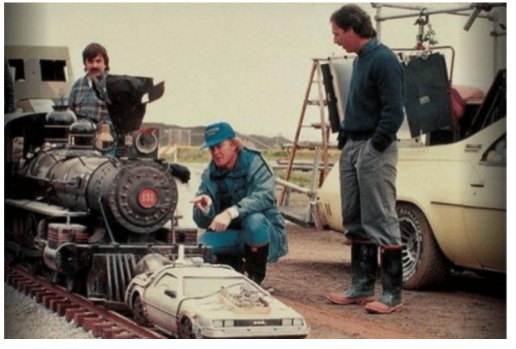
$$\overline{x_2} = \underbrace{\begin{bmatrix} h_{11} & h_{13} & h_{13} \\ h_{21} & h_{22} & h_{23} \\ h_{31} & h_{32} & h_{33} \end{bmatrix}}_{H} \cdot \overline{x_1}$$

Homography

UNIVERSITÀ DI PARMA

- How many matches we need?
  - 9 unknowns? ⟶ no, we will never be able to solve scale
  - 8 unknowns ⟶ yes!
- Each match ⟶ 2 equations
- We need (at least) 4 correspondencies!

$$h = \begin{bmatrix} h_{11} \\ h_{12} \\ h_{13} \\ h_{21} \\ h_{22} \\ h_{23} \\ h_{31} \\ h_{32} \\ h_{33} \end{bmatrix}$$



Homography

- We can solve using:

$$\begin{cases} x_2 = h_{11}x_1 + h_{12}y_1 + h_{13} \\ y_2 = h_{21}x_1 + h_{22}y_1 + h_{23} \\ z_2 = h_{31}x_1 + h_{32}y_1 + h_{33} \end{cases}$$

- For Euclidean coordinates

$$\begin{cases} x_2' = \dfrac{x_2}{z_2} = \dfrac{h_{11}x_1 + h_{12}y_1 + h_{13}}{h_{31}x_1 + h_{32}y_1 + h_{33}} \\ y_2' = \dfrac{y_2}{z_2} = \dfrac{h_{21}x_1 + h_{22}y_1 + h_{23}}{h_{31}x_1 + h_{32}y_1 + h_{33}} \end{cases}$$

Homography

- 2nd step

$$\begin{cases} x_2'(h_{31}x_1 + h_{32}y_1 + h_{33}) = h_{11}x_1 + h_{12}y_1 + h_{13} \\ y_2'(h_{31}x_1 + h_{32}y_1 + h_{33}) = h_{21}x_1 + h_{22}y_1 + h_{23} \end{cases}$$

- Ordering

$$\begin{cases} -h_{11}x_1 - h_{12}y_1 - h_{13} + h_{31}x_1x_2' + h_{32}y_1x_2' + h_{33}x_2' = 0 \\ -h_{21}x_1 - h_{22}y_1 - h_{23} + h_{31}x_1y_2' + h_{32}y_1y_2' + h_{33}y_2' = 0 \end{cases}$$

Homography

- This for a single match

$$\begin{cases} -h_{11}x_1 - h_{12}y_1 - h_{13} + h_{31}x_1x_2' + h_{32}y_1x_2' + h_{33}x_2' = 0 \\ -h_{21}x_1 - h_{22}y_1 - h_{23} + h_{31}x_1y_2' + h_{32}y_1y_2' + h_{33}y_2' = 0 \end{cases}$$

- For all

$$A * h = 0$$

Homography

- This for a single match

$$\begin{cases} -h_{11}x_1 - h_{12}y_1 - h_{13} + h_{31}x_1x_2{}' + h_{32}y_1x_2{}' + h_{33}x_2{}' = 0 \\ -h_{21}x_1 - h_{22}y_1 - h_{23} + h_{31}x_1y_2{}' + h_{32}y_1y_2{}' + h_{33}y_2{}' = 0 \end{cases}$$

- For all

$$A = \begin{bmatrix} -x_1{}^{(1)} & -y_1{}^{(1)} & -1 & 0 & 0 & 0 & x_1x_2{}'^{(1)} & y_1x_2{}'^{(1)} & x_2{}'^{(1)} \\ 0 & 0 & 0 & -x_1{}^{(1)} & -y_1{}^{(1)} & -1 & x_1y_2{}'^{(1)} & y_1y_2{}'^{(1)} & y_2{}'^{(1)} \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ -x_1{}^{(n)} & -y_1{}^{(n)} & -1 & 0 & 0 & 0 & x_1x_2{}'^{(n)} & y_1x_2{}'^{(n)} & x_2{}'^{(n)} \\ 0 & 0 & 0 & -x_1{}^{(n)} & -y_1{}^{(n)} & -1 & x_1y_2{}'^{(n)} & y_1y_2{}'^{(n)} & y_2{}'^{(n)} \end{bmatrix}$$

Homography

- Again we can use SVD decomposition to find best fit

$$A = UDV^T$$

- Last column of V is the solution

- Both OpenCV and Eigen provide a SVD solver:

  cv::SVD::compute(const Mat & A, Mat & D, Mat & U, Mat & Vt)

- Not enough we need to normalize result

Image Stitching

UNIVERSITÀ DI PARMA

- Main steps
  - Acquire multiple images
  - Get transformation from first image to following one
  - Reproject that image onto the previous one
  - Blend them in the result
  - Until we have images ⟶ repeat

Reprojection

UNIVERSITÀ DI PARMA

- We now have H
- Simply use

$$\overline{x_2} = H \cdot \overline{x_1}$$

- Basically we fill plane of first image adding other pixels

Image Stitching

UNIVERSITÀ DI PARMA

- Main steps
  - Acquire multiple images
  - Get transformation from first image to following one
  - Reproject that image onto the previous one
  - Blend them in the result
  - Until we have images ⟶ repeat

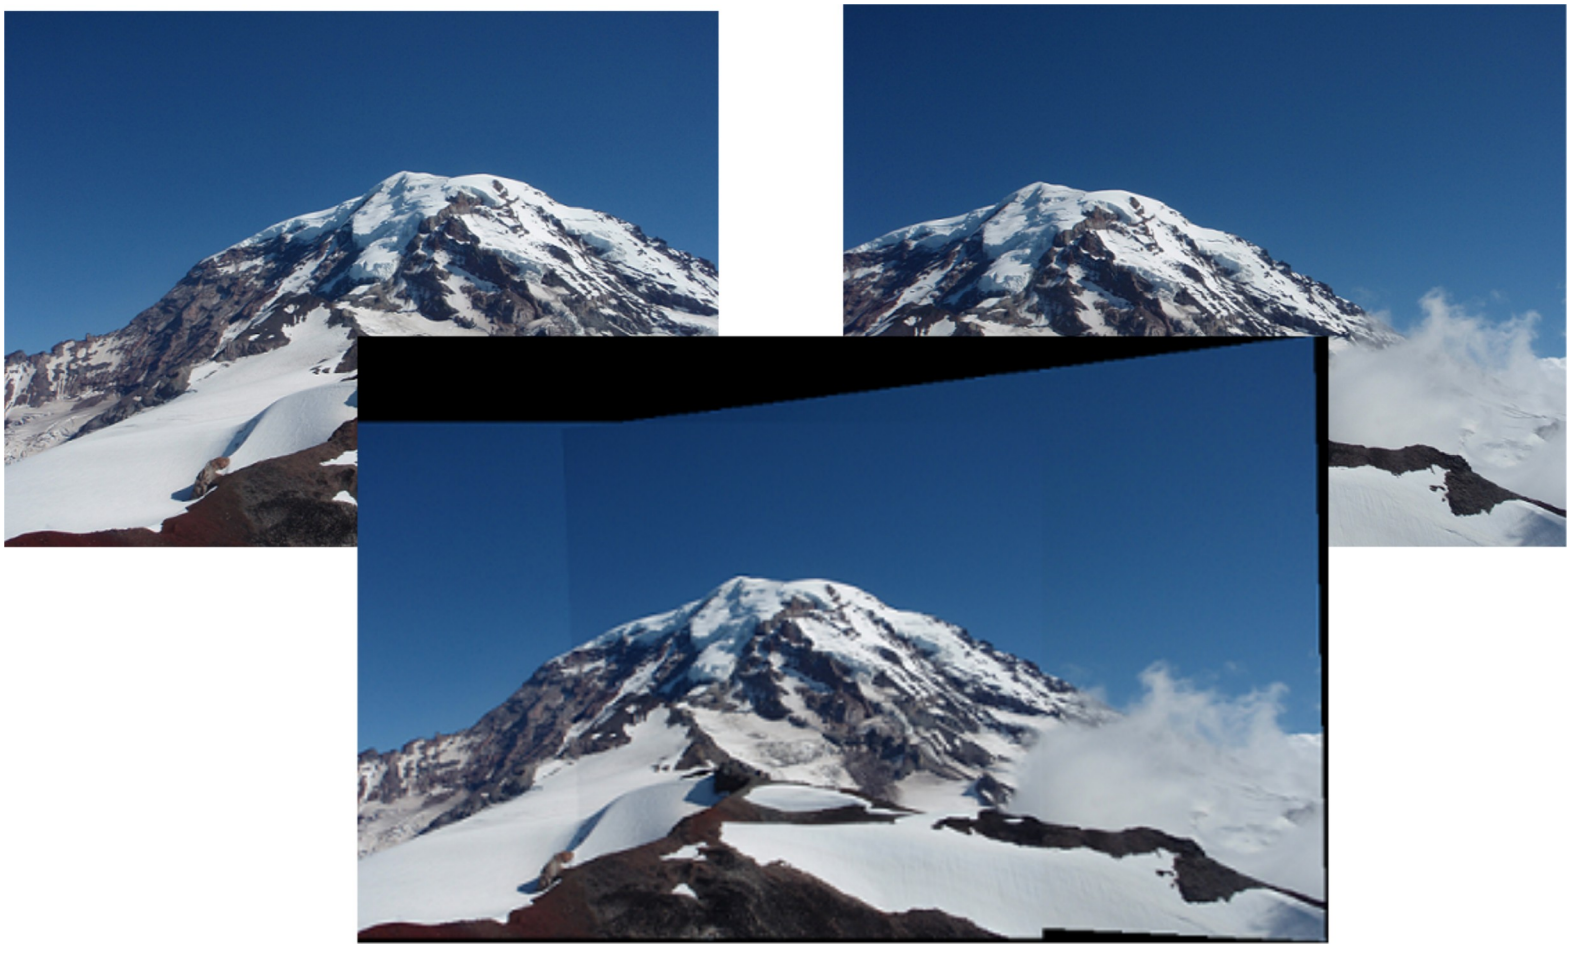
Image blending

UNIVERSITÀ DI PARMA

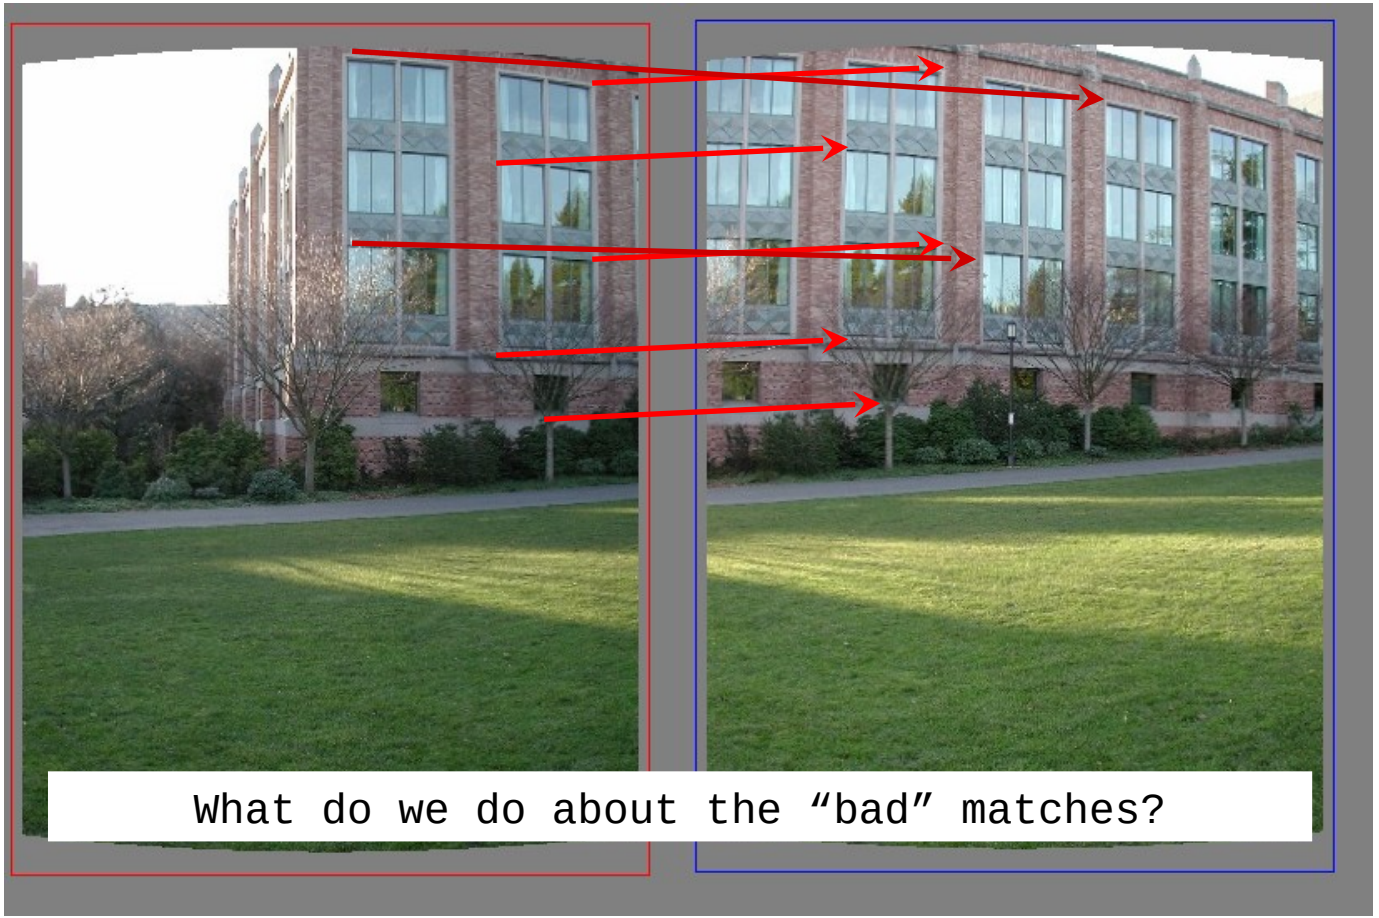
- Consider bilinear interpolation
  - Previous equation gives floating point results
- When we have multiple points from different images use an average

Image stitching

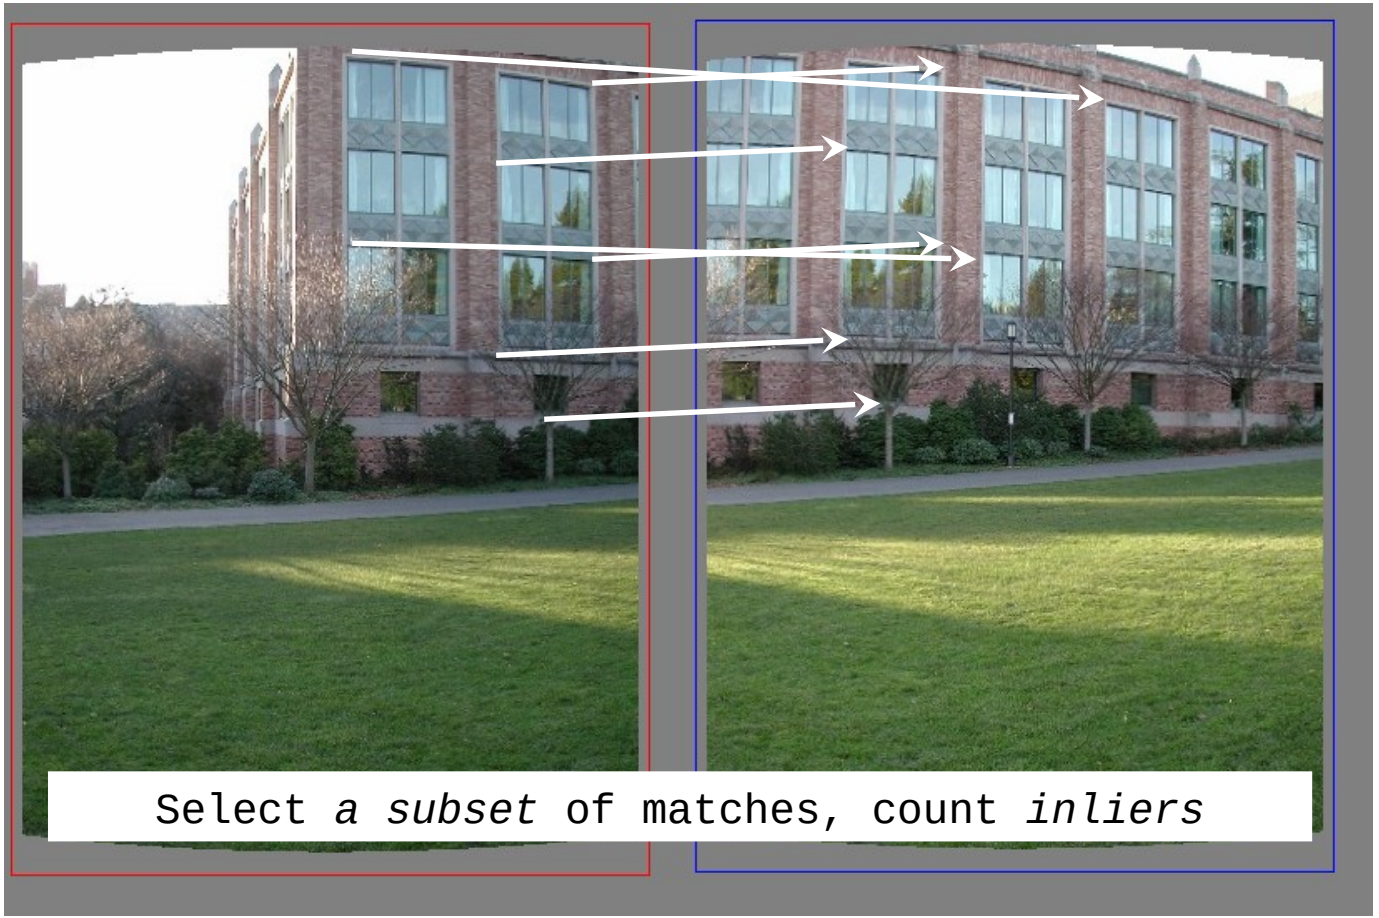
UNIVERSITÀ
DI PARMA



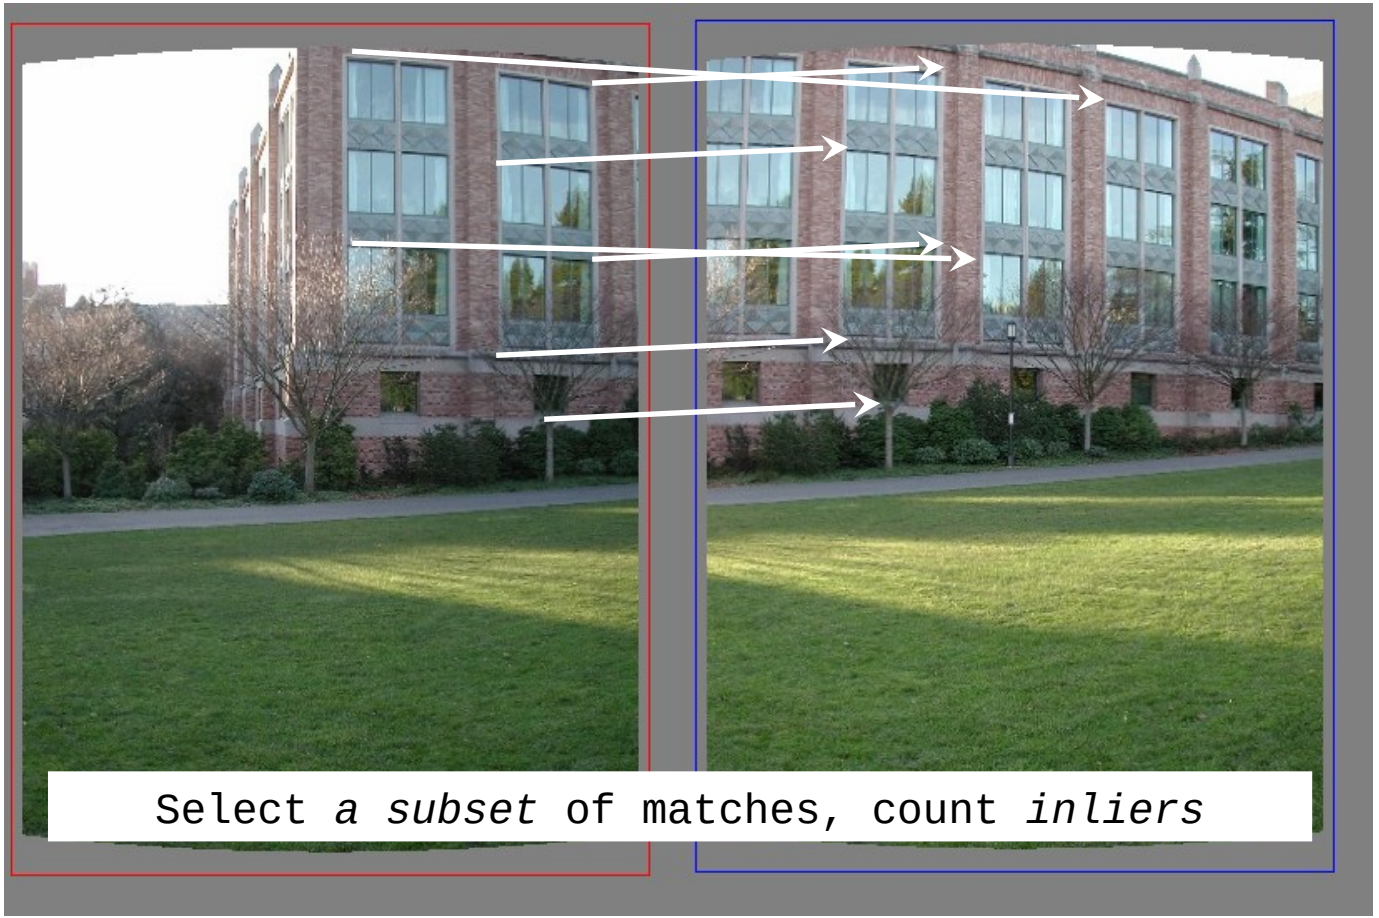
Issues



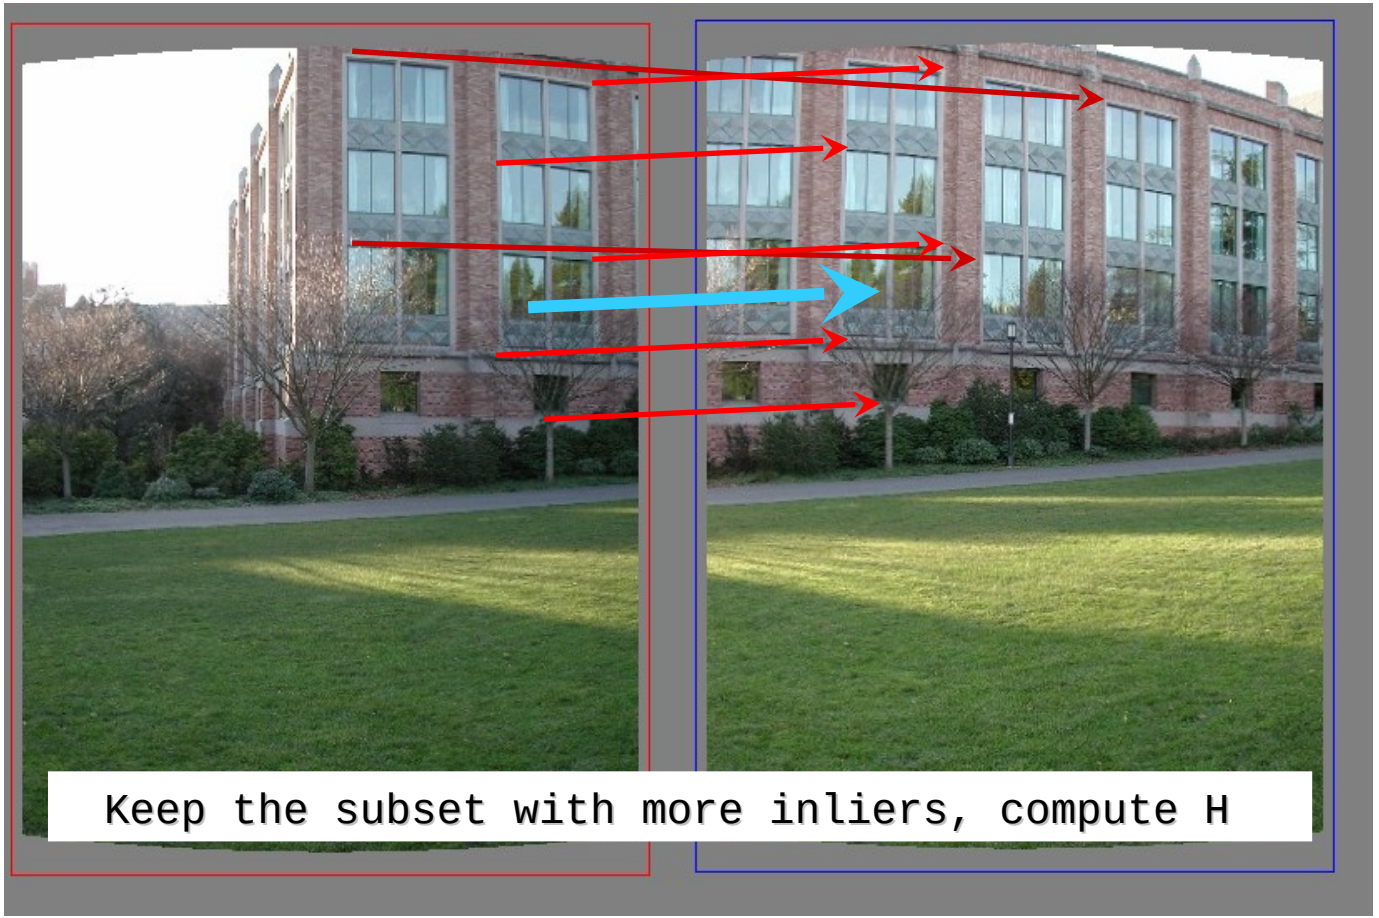
Issues



Issues



Issues



RANSAC

- Randomly select 4 matches
- Compute H from those matches
- Count how many inliers are obtained assuming

$$\|p_2', H\, p_i\| < \varepsilon$$

- Repeat N times
- At the end recompute H using all inliers of the best match!

UNIVERSITÀ DI PARMA

Feature Matching

Question time!
